

Electroweak and QCD corrections to off-shell tZj production at the LHC

Giovanni Pelliccioli
Max-Planck-Institut für Physik

Introduction

Improving the **perturbative description** of full off-shell top-quark processes at colliders is a mandatory step for realistic predictions, though not the only one (parton-shower matching, hadronisation, ...).

Computing **NLO QCD** and **EW** corrections is **not straightforward**:

1. **high-multiplicity** final states,
2. **complicated resonant** structures,
3. **non-resonant effects** and **spin-correlations** must be included,
4. **mixing of EW and QCD** corrections at a given order.

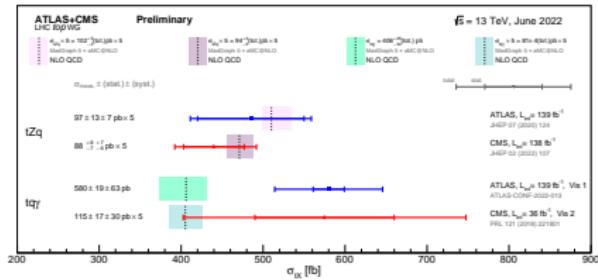

This talk has a focus on

→ **tZj** at the LHC (mostly based on Denner GP Schwan JHEP 10 (2022) 125 [2207.11264])

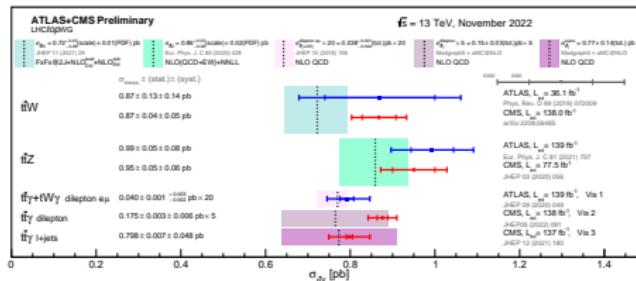

Rare processes

Rare processes at the LHC: weak boson(s) V in association with

- ★ a single (anti)top quark: $tVj/\bar{t}Vj \rightarrow$ EW induced

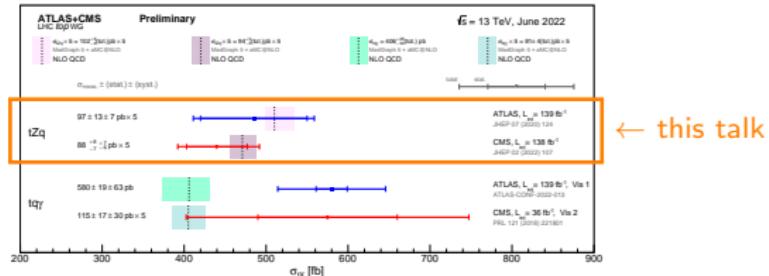

- ★ a top-antitop pair: $t\bar{t}V \rightarrow$ QCD induced (but large EW contribution)

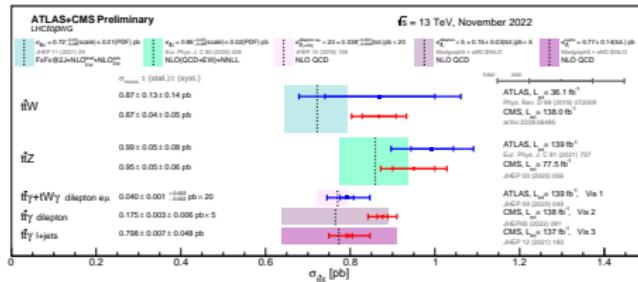

Rare processes

Rare processes at the LHC: weak boson(s) V in association with

- ★ a single (anti)top quark: $tVj/\bar{t}Vj \rightarrow$ EW induced

- ★ a top-antitop pair: $t\bar{t}V \rightarrow$ QCD induced (but large EW contribution)

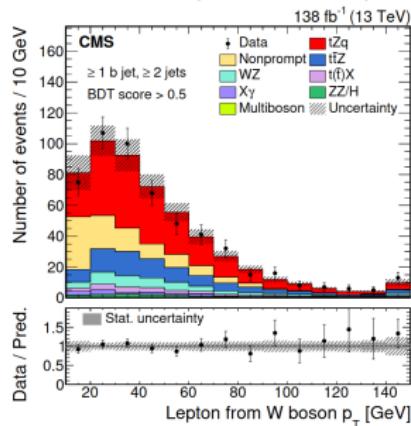

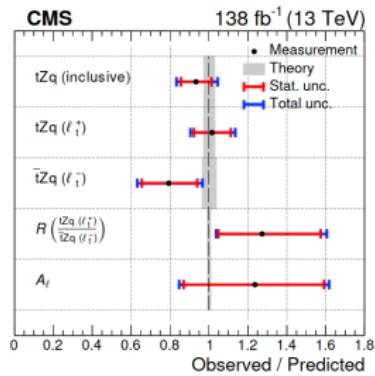

Theory motivations and experimental measurements

Gives access to top-quark-to-Z-boson (more directly than $t\bar{t}Z$), triple-gauge (WWZ) and Wtb couplings to constrain new physics.

EW-induced process: top quark strongly polarised [Mahlon Parke 9912458].

Observed with Run-2 data [CMS 1812.05900, ATLAS 2002.07546].

First differential-cross-section measurement [CMS 2111.02860] (figure below)

Beyond the Standard Model

Phenomenological studies with **vector-like top partners** [Reuter Tonini 1409.6962],
anomalous couplings [Li et al. 1103.5122, Kidonakis 1712.01144, Liu Moretti 2010.05148].

Broad **SMEFT** interpretation for tZj and tHj [Degrade et al. 1804.07773].

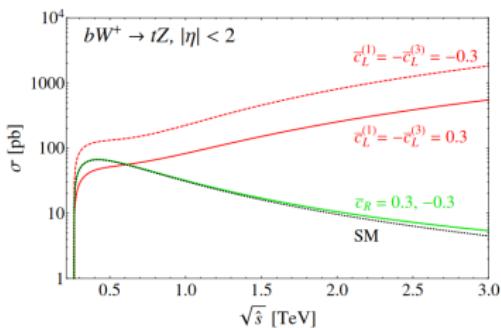

Owing to embedded $bW^+ \rightarrow tZ$ scattering, high sensitivity to anomalous Z-fermions and triple-gauge couplings, controlling leading energy-growth of amplitude:

$$\mathcal{A}_{(-,0,-,0)} \propto \sqrt{s(s+t)} \left(g_L^{Zb} - g_L^{Zt} + g^{WZ} \right)$$

Anomalous couplings lead to
gauge/unitarity violations

[Dror et al. 1511.03674, Maltoni et al. 1904.05637]

figure from [Dror et al. 1511.03674]

Standard Model predictions

So far, **SM modelling** with on-shell approx., **off-shell effects needed** in fiducial regions:

NLO QCD: narrow-with approximation (NWA) [[Campbell Ellis Röntsch 1302.3856](#)].

NLO QCD+EW, on-shell: on-shell top , off-shell Z [[Pagani Tsinikos Vryonidou 2006.10086](#)].

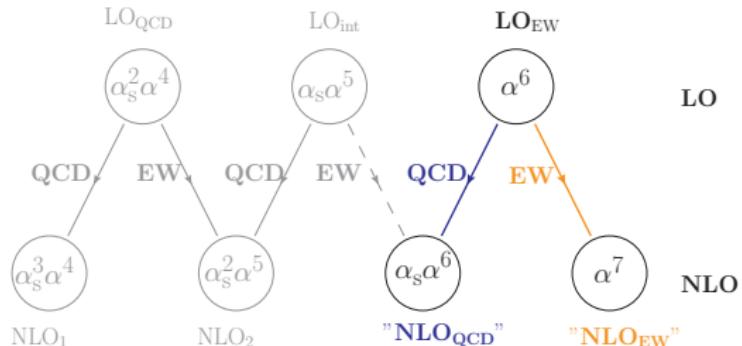

PS matching: NLO QCD + QCD shower, LO decays [[Pagani Tsinikos Vryonidou 2006.10086](#)]

NLO, full off-shell: NLO EW + QCD [[Denner GP Schwan 2207.11264](#)] in the 3ℓ channel.

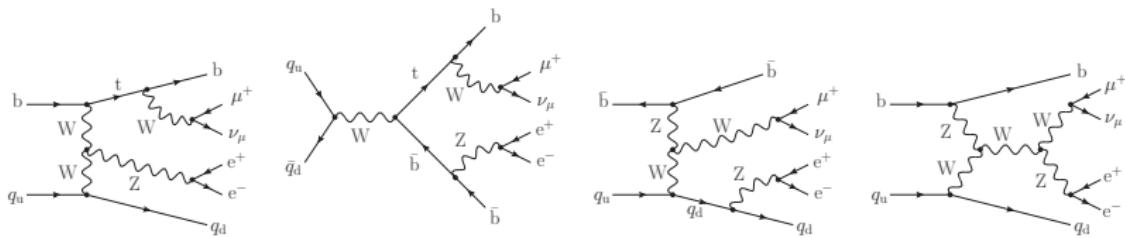

Soft-gluon resummation: exact NLO + soft-gluon corr. [[Kidonakis Yamanaka 2210.09542](#)].

LO contributions

$p p \rightarrow e^+ e^- \mu^+ \nu_\mu j_b J + X$
 $j_b = b\text{-tagged jet}$
 $J = \text{any jet}$

LO: LO_{QCD} non-resonant, LO_{int} vanishes (CKM unit matrix), single-top in LO_{EW} .
 Channels with initial states $q\bar{q}$, qb

t-channel resonant

s-channel resonant

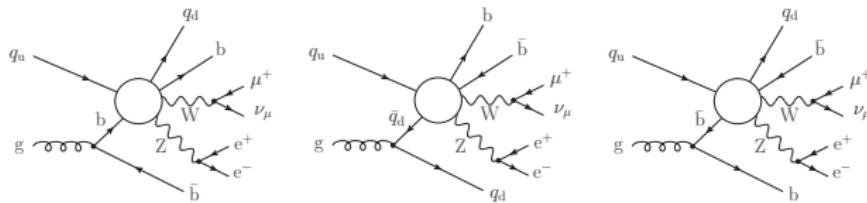

non-resonant

VBS-like

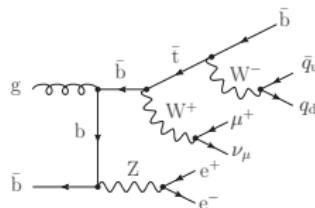

NLO contributions

NLO QCD and EW: genuine corrections to LO EW (no interference).
Real channels with initial states $q\bar{q}$, qb , gq , γq , gb , γb .

Not possible to distinguish between ***t*-channel** and ***s*-channel** contributions at NLO:

Fiducial-volume for **top quark** contaminated by **hadronically decaying antitop** ($\gamma\bar{b}$, gb):

The same holds for the charged-conjugated process: **very large** correction ($\approx +10\%$).
Irreducible bkg that can only be treated with jet vetoes/ special cuts.

Setup

$p p \rightarrow e^+ e^- \mu^+ \nu_\mu j_b J + X$ at $\mathcal{O}(\alpha_s \alpha^6)$ and $\mathcal{O}(\alpha^7)$ [Denner GP Schwan 2207.11264]

- full tree-level and one-loop amplitudes: RECOLA1 [Actis et al. 1605.01090]
- 1-loop tensor-integral reduction and evaluation: COLLIER [Denner et al. 1604.06792]
- multi-channel integration with MoCANLO in-house Monte Carlo
- dipole subtraction of IR singularities [Catani Seymour 9605323, Dittmaier 9904440]
- complex-mass scheme [Denner et al. 9904472] for W, Z, top
- NNPDF3.1 NNLO LUXQED PDFs (photon included, [Bertone et al. 1712.07053]);
- Γ_t computed including NLO QCD+EW corrections [Basso et al. 1507.04676].

Selections mimic those of [ATLAS 2002.07546].

Jets: b-jets (j_b) and light jets (j) clustered with k_t algorithm [Catani et al. Nucl.Phys.B406(1993)] and $R = 0.4$, $N_b \geq 1$, $N_{j_b} + N_j \geq 2$, $p_{T,j_b}, p_{T,j} > 35\text{GeV}$, $|y_{j_b}| < 2.5$, $|y_j| < 4.5$

Leptons 3 dressed leptons clustered with k_t algorithm and $R = 0.1$, $p_{T,\ell_1} > 28\text{GeV}$, $p_{T,\ell} > 20\text{GeV}$, $|y_\ell| < 2.5$, $M_{e^+ e^-} > 30\text{GeV}$, $\Delta R_{\ell J} > 0.4$

Central-scale choice: $\mu_0 = (M_{T,t} + M_{T,z})/6$ (inspired by [Pagani et al. 2006.10086]).

Reconstruction of top-quark and spectator-jet observables

Missing p_T owing to single neutrino: reconstructing top quark is possible.

Strategy for single-top [Cao et al. 0504230], used in differential tZj analysis [CMS 2111.02860].

Identify top-decay (j_t) and spectator (j_s) jets (recall that $N_b \geq 1$ and $N_{j_b} + N_j \geq 2$):

- ▶ $N_{j_b} + N_j = 2$:
 - $N_{j_b} = 1, N_j = 1$: no ambiguity for j_t, j_s
 - $N_{j_b} = 2$: minimize $|M_{j_b \ell \nu^{rec}} - m_{top}|$ for j_t , other is j_s
- ▶ $N_{j_b} + N_j > 2$:
 - $N_{j_b} = 1$: no ambiguity for j_t , hardest- p_T light jet is j_s
 - $N_{j_b} \geq 2$: minimize $|M_{j_b \ell \nu^{rec}} - m_{top}|$ for j_t , hardest- p_T light jet is j_s

Reconstruct neutrino with resonance-aware on-shell requirement $M_{\ell \nu^{rec}}^2 = M_W^2$ (quadratic eq.):

- if complex sol., take real part
- if 2 real sol., minimize $|M_{j_t \ell \nu^{rec}} - m_{top}|$ ($M_{j_b \ell \nu^{rec}}$ if ambiguity for j_t)

Integrated cross-sections

Fiducial cross-sections

[Denner GP Schwan 2207.11264]

- Sizeable QCD and EW corrections.
- QCD-scale (downward) uncertainty diminished from LO to NLO QCD.

Contribution	Default setup		Z-peak setup		
	σ [fb]	δ [%]	σ [fb]	δ [%]	
$\mathcal{O}(\alpha^6)$ = LO	0.6416	+8.9 % -13.5 %	100.0	0.5846 +9.0 % -13.5 %	100.0
$\mathcal{O}(\alpha_s \alpha^6)$	0.1987(5)		31.0	0.1788(5)	30.6
$\mathcal{O}(\alpha^7)$	-0.0416(6)		-6.5	-0.0499(6)	-8.5
NLO QCD	0.8402(5)	+8.6 % -3.9 %	131.0	0.7634(5) +8.6 % -3.9 %	130.6
NLO EW	0.5999(6)	+9.4 % -13.9 %	93.5	0.5348(6) +9.4 % -13.9 %	91.5
NLO QCD+EW	0.7986(8)	+9.4 % -4.2 %	124.5	0.7135(8) +9.8 % -4.4 %	122.0

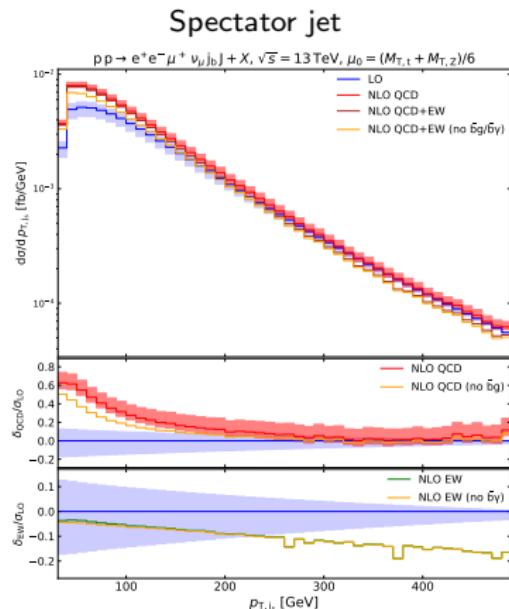

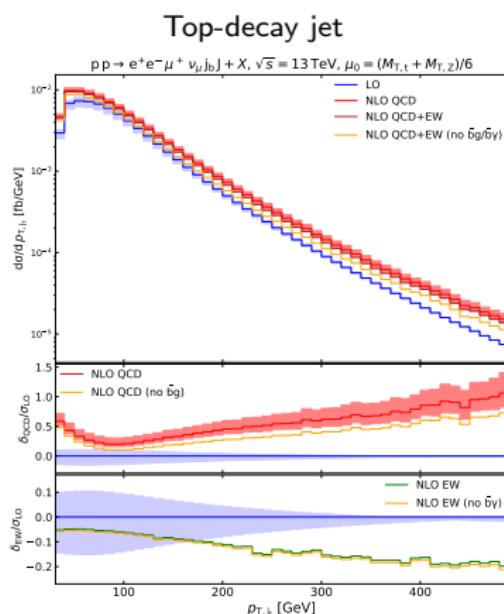

Z-peak setup: $81\text{GeV} < M_{e^+e^-} < 101\text{GeV}$ (default: $M_{e^+e^-} > 30\text{GeV}$).

Off-shell [Denner GP Schwan 2207.11264] vs on-shell [Pagani et al. 2006.10086] in Z-peak setup: same EW correction (relative to NLO QCD), differences at NLO QCD.

	on-shell	off-shell* (w/o decay corr.)	off-shell*
NLO QCD/LO	1.24	1.289	1.195
(NLO QCD+EW)/NLO QCD	0.93	0.919	0.924

* excluded $\bar{b}\gamma$, $\bar{b}g$ channels

Transverse-momentum of jets

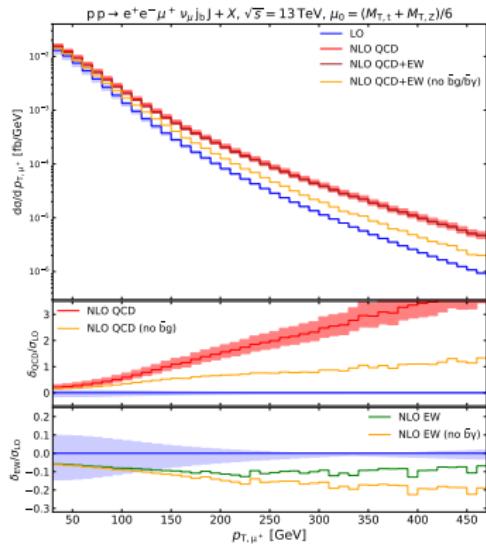

- ▶ increasing positive QCD corrections (up to 100%) due to LO suppression
- ▶ EW-Sudakov enhancement in the tail

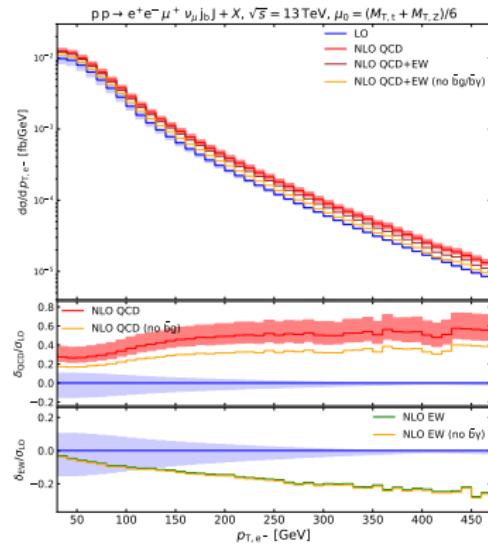

- ▶ decreasing QCD corrections ($\rightarrow 0$ at large p_T), no LO suppression
- ▶ tZ system recoils against j_s (Z typically soft or close to top)

Transverse-momentum of leptons

Antimuon (top-quark decay)

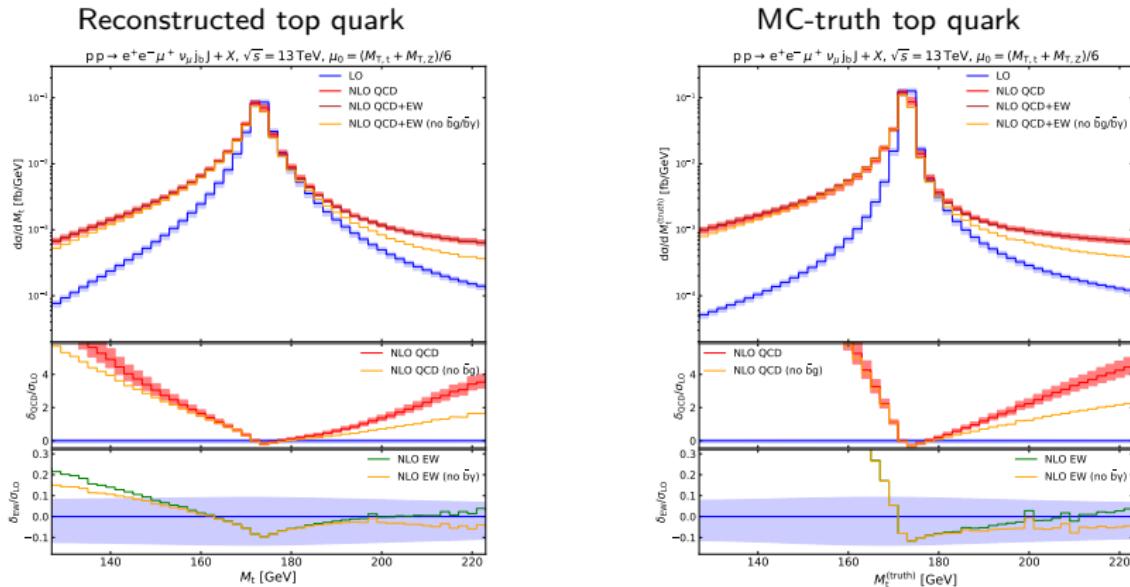

Electron (Z-boson decay)

- ▶ EW corr. flat for μ^+ : $\bar{b}\gamma$ contributions cancel NLO EW to LO channels.
- ▶ dominance of EW Sudakov logs for e^-
- ▶ QCD effects stronger for μ^+ than for Z-decay leptons

Invariant-mass of the top quark

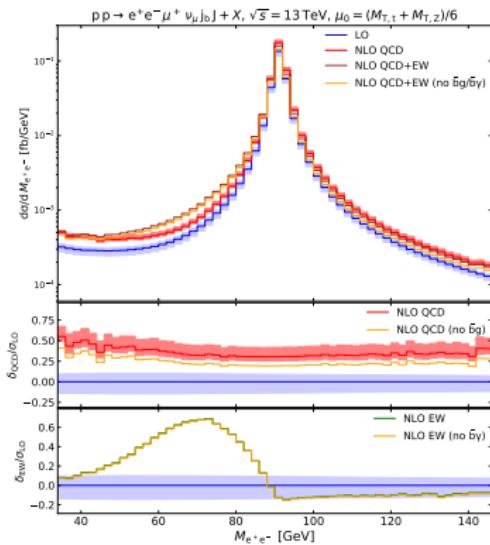

Reconstruction mostly affects radiative-return tail at low mass (both EW and QCD)

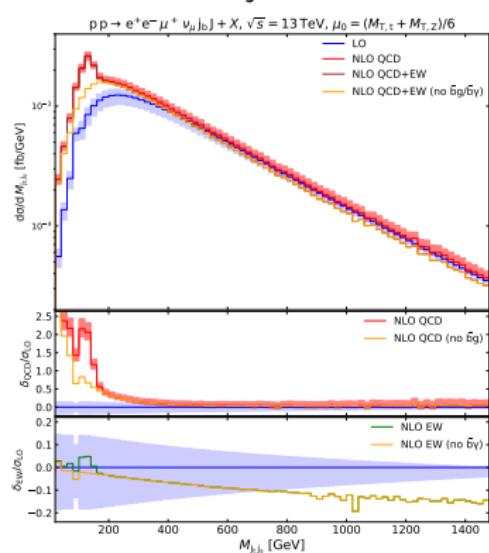

Negative NLO corr. at peak, positive otherwise

Invariant-mass of the Z boson and the di-jet system

Z-boson

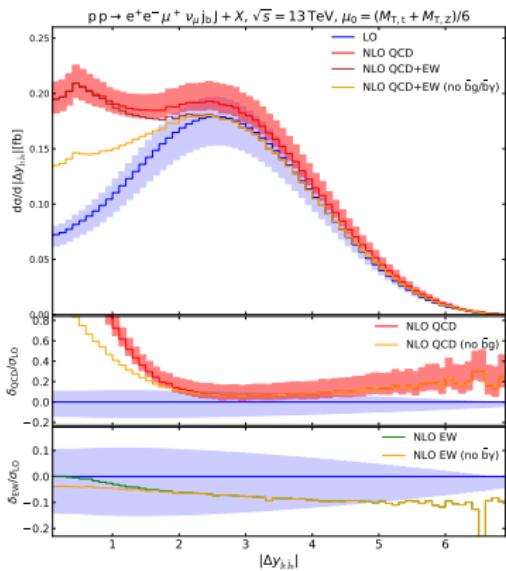

Di-jet

- ▶ rather flat QCD corrections
- ▶ large EW radiative return below peak (soft photons)
- ▶ hadronic-antitop peak at 165 GeV (below m_{top} , owing to jet-identification)

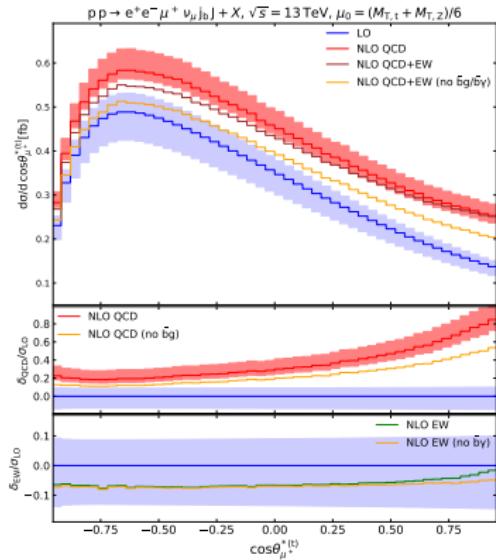

Rapidity and angular observables

Rapidity separation between top-decay jet and spectator jet

- ▶ tZ topology peaks at $|\Delta y_{j,tj}| \approx 2.5$
- ▶ large hadronic-antitop contamination for $|\Delta y_{j,tj}| < 1$

Polarisation-sensitive polar angle of the antimuon in the top-quark rest frame

- ▶ definition similar to helicity basis
- ▶ depletion of anti-collinear region due to cuts, top-quark mostly left handed

Conclusions

Essential to properly model off-shell/decay effects in top-quark-associated processes for upcoming fiducial and differential LHC measurements .

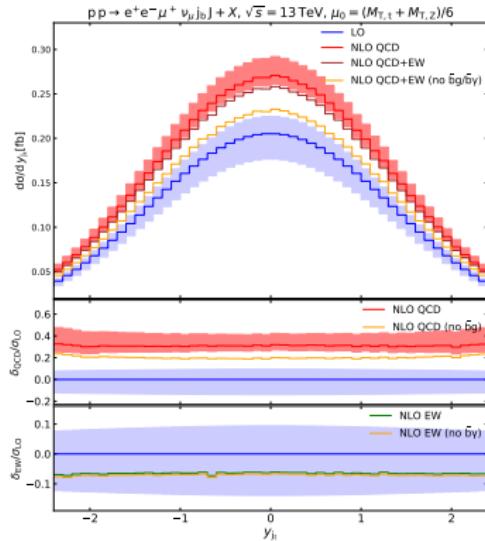

Take-home messages from tZj:

- ▶ QCD-scale uncertainties not so reduced owing to EW production mechanism
- ▶ NLO EW corrections negative and scale-independent
- ▶ EW-Sudakov enhancement in tails of p_T and mass distributions.
- ▶ opening of new sub-processes with higher-orders
- ▶ overlap with other resonance structures in fiducial volume ($\bar{t}WZ$)
- ▶ combined NLO may exceed scale-unc. of the NLO_{QCD} , not severe in tZj
- ▶ off-shell effects relevant in the tails of several distributions (mass, p_T)
- ▶ both EW and QCD corrections change distribution shapes (also angular ones)
