# OUTLINE

- **Aspects of  $2 \rightarrow 2$  scattering amplitudes in the high-energy limit**
- **The Balitsky-JIMWLK equation and the three loop amplitude**
- **Comparison between Regge and infrared factorization**

***In collaboration with Simon Caron-Huot and Einan Gardi,***

***Based on arXiv:1701.05241***

# ASPECTS OF $2 \rightarrow 2$ SCATTERING AMPLITUDES IN THE HIGH-ENERGY LIMIT

# 2 → 2 SCATTERING AMPLITUDES IN THE HIGH-ENERGY LIMIT

- Calculation of scattering amplitudes at high order in perturbation theory is one of the main ingredients for the program of precision physics at the LHC

$$\mathcal{M} = 4\pi\alpha_s \left[ \mathcal{M}^{(0)} + \frac{\alpha_s}{4\pi} \mathcal{M}^{(1)} + \left( \frac{\alpha_s}{4\pi} \right)^2 \mathcal{M}^{(2)} + \dots \right]$$

- Amplitudes are **complicated functions** of the **kinematical invariants**, their calculation is non-trivial, and it is subject of intense study.
  - Express **Feynman integrals** in terms of **known functions** (harmonic polylogarithms, elliptic integrals, etc)
  - Amplitudes contains **infrared divergences**, which must cancel when summing virtual and real corrections.

# 2 → 2 SCATTERING AMPLITUDES IN THE HIGH-ENERGY LIMIT

- Information and constraints can be obtained by

considering **kinematical limits**:

- it **reduces** the number of invariants;
- it helps identifying **factorisation properties** and **iterative structures** of the amplitude;
- it may be **relevant for phenomenology**: because of soft and collinear enhancement, amplitudes in specific kinematic limit **develops large logarithms**, which may spoil the convergence of the perturbative expansion in that region of the parameter space.

- Consider 2 → 2 scattering amplitudes in the **high-energy limit**:

$$s = (p_1 + p_2)^2 \gg -t = -(p_1 - p_4)^2 > 0$$

- The amplitude becomes a function of the ratio  $|s/t|$ ; here we consider the leading power term in this expansion

$$\mathcal{M}(s, t, \mu) = \mathcal{M}_{LP} \left( \frac{s}{-t}, \frac{-t}{\mu^2} \right) + \mathcal{O} \left( \frac{-t}{s} \right)$$

# 2 → 2 SCATTERING AMPLITUDES IN THE HIGH-ENERGY LIMIT

- Consider, as an example, the **gluon-gluon** scattering amplitude at tree level:

- In the high-energy limit only the **second diagram** contributes at leading power. The amplitude is simply

$$\mathcal{M}(s, t) = 4\pi\alpha_s \sum_{n=0}^{\infty} \left(\frac{\alpha_s}{\pi}\right)^n \mathcal{M}^{(n)}(s, t), \quad \mathcal{M}_{ij \rightarrow ij}^{(0)} = \frac{2s}{t} (T_i^b)_{a_1 a_4} (T_j^b)_{a_2 a_3} \delta_{\lambda_1 \lambda_4} \delta_{\lambda_2 \lambda_3}.$$

- The amplitude at higher orders contains **logarithms** of the ratio  $|s/t|$ . In the sixties the dominant behaviour in the high-energy limit was characterised in terms of **Regge poles** and **cuts**. These can now be studied in the context of QCD. One has

**Regge, Gribov**

$$\mathcal{M}_{ij \rightarrow ij}|_{\text{LL}} = \left(\frac{s}{-t}\right)^{\frac{\alpha_s}{\pi} C_A \alpha_g^{(1)}(t)} 4\pi\alpha_s \mathcal{M}_{ij \rightarrow ij}^{(0)},$$

- where the function  $\alpha_g(t)$  is known as the **Regge trajectory**:

$$\alpha_g(t) = \sum_{n=1}^{\infty} \left(\frac{\alpha_s}{\pi}\right)^n \alpha_g^{(n)}(t), \quad \alpha_g^{(1)}(t) = \frac{r_\Gamma}{2\epsilon} \left(\frac{-t}{\mu^2}\right)^{-\epsilon} \stackrel{\mu^2 \rightarrow -t}{=} \frac{r_\Gamma}{2\epsilon},$$

- and  $r_\Gamma$  is a ubiquitous **1-loop factor**:

$$r_\Gamma = e^{\epsilon\gamma_E} \frac{\Gamma(1-\epsilon)^2 \Gamma(1+\epsilon)}{\Gamma(1-2\epsilon)} \approx 1 - \frac{1}{2} \zeta_2 \epsilon^2 - \frac{7}{3} \zeta_3 \epsilon^3 + \dots$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: ANALYTIC STRUCTURE

- Beyond **LL** the structure of factorisation of high-energy logarithms becomes **much richer**.
- We need to investigate more carefully the **analytic structure** of the amplitude, which can be summarised via the **dispersion relation**

$$\mathcal{M}(s, t) = \frac{1}{\pi} \int_0^\infty \frac{d\hat{s}}{\hat{s} - s - i0} D_s(\hat{s}, t) + \frac{1}{\pi} \int_0^\infty \frac{d\hat{u}}{\hat{u} + s + t - i0} D_u(\hat{u}, t)$$

- where  $D_s$  and  $D_u$  are discontinuities of  $\mathcal{M}(s, t)$  in the **s-** and **u-** channels.

Regge, Gribov, .. see also Collins

- $D_s$  and  $D_u$  are real (**spectral density of positive energy states** propagating in the **s-** and **u-** channels). Parametrise them as a **sum of power laws** by means of a **Mellin transformation**:

$$a_j^s(t) = \frac{1}{\pi} \int_0^\infty \frac{d\hat{s}}{\hat{s}} D_s(\hat{s}, t) \left( \frac{\hat{s}}{-t} \right)^{-j}, \quad D_s(s, t) = \frac{1}{2i} \int_{\gamma-i\infty}^{\gamma+i\infty} dj a_j^s(t) \left( \frac{s}{-t} \right)^j,$$

- Note that the reality condition of  $D_s(s, t)$  implies that the Fourier coefficients admit

$$(a_{j^*}^s(t))^* = a_j^s(t),$$

- Substituting the inverse transform into the dispersive representation, swapping the order of integration and integrating over  $\hat{s}$  and  $\hat{u}$ , one obtains a Mellin representation of the amplitude:

$$\mathcal{M}(s, t) = \frac{-1}{2i} \int_{\gamma-i\infty}^{\gamma+i\infty} \frac{dj}{\sin(\pi j)} \left( a_j^s(t) \left( \frac{-s - i0}{-t} \right)^j + a_j^u(t) \left( \frac{s + t - i0}{-t} \right)^j \right).$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: ANALYTIC STRUCTURE

- The dispersion relation allows us to infer useful properties concerning the projection of the amplitude onto **eigenstates of signature**, that is **crossing symmetry**  $s \leftrightarrow u$ :

$$\mathcal{M}^{(\pm)}(s, t) = \frac{1}{2} \left( \mathcal{M}(s, t) \pm \mathcal{M}(-s - t, t) \right).$$

- $\mathcal{M}^{(+)}$  and  $\mathcal{M}^{(-)}$  are referred respectively to as the **even** and **odd amplitudes**. Restricting to the region  $s > 0$  and working to leading power as  $s \gg |t|$ , the formula then evaluates to

$$\mathcal{M}^{(+)}(s, t) = i \int_{\gamma-i\infty}^{\gamma+i\infty} \frac{dj}{\sin(\pi j)} \cos\left(\frac{\pi j}{2}\right) a_j^{(+)}(t) e^{jL},$$

$$\mathcal{M}^{(-)}(s, t) = \int_{\gamma-i\infty}^{\gamma+i\infty} \frac{dj}{\sin(\pi j)} \sin\left(\frac{\pi j}{2}\right) a_j^{(-)}(t) e^{jL},$$

- Where  $a_j^{(\pm)}(t) = 1/2(a_j^s(t) \pm a_j^u(t))$ , and  $L$  is the natural signature-even combination of logs:

$$L \equiv \log \left| \frac{s}{t} \right| - i \frac{\pi}{2} = \frac{1}{2} \left( \log \frac{-s - i0}{-t} + \log \frac{-u - i0}{-t} \right).$$

- The reality properties of  $a_j^s(t)$ ,  $a_j^u(t)$  implies that  $\mathcal{M}^{(+)}$  and  $\mathcal{M}^{(-)}$  are **imaginary** and **real**, respectively, when expressed in **powers** of  $L$  (not  $\log |s/t|$ ).
- At leading power in  $t/s$  the **Mellin variable**  $j$  is identical to the **spin**  $j$  which enters conventional **partial wave expansion**.
- One could easily extend the discussion to **subleading powers** replacing the Mellin transform by the partial wave expansion. For example,  $(s/t)^{-j-1}$  and  $(s/t)^j$  would be replaced respectively by the associated **Legendre function**  $Q_j(1 + 2s/t)$  and **Legendre polynomials**  $P_j(1 + 2s/t)$ .

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: ANALYTIC STRUCTURE

- The simplest conceivable asymptotic behaviour is a pure **power law**, whose Mellin transform is a simple **Regge pole**, namely

$$a_j^{(-)}(t) \simeq \frac{1}{j-1-\alpha(t)} \quad \Rightarrow \quad \mathcal{M}^{(-)}(s, t)|_{\text{Regge pole}} \simeq \frac{\pi}{\sin \frac{\pi \alpha(t)}{2}} \frac{s}{t} e^{L \alpha(t)} + \dots$$

- where the ellipsis indicated **subleading** contributions. Regge poles give the correct behaviour of the  $2 \rightarrow 2$  amplitude at **LL** in perturbation theory, where  $\alpha(t)$  is interpreted as the **gluon Regge trajectory**,  $\alpha(t) = \alpha_g(t) \sim \mathcal{O}(\alpha_s(t))$ .
- In order to get the precise behavior at higher orders in perturbation theory one needs to take into account the contribution of **Regge cuts**, which arises from  $a_j^{(-)}(t)$  of the form

$$a_j^{(-)}(t) \simeq \frac{1}{(j-1-\alpha(t))^{1+\beta(t)}} \quad \Rightarrow \quad \mathcal{M}^{(-)}(s, t)|_{\text{Regge cut}} \simeq \frac{\pi}{\sin \frac{\pi \alpha(t)}{2}} \frac{s}{t} \frac{L^{\beta(t)} e^{L \alpha(t)}}{\Gamma(1+\beta(t))} + \dots$$

- which has a **branch point** from  $1 + \alpha(t)$  to  $-\infty$ , or a multiple pole if  $\beta(t)$  is a positive integer.
- While Regge poles contribute to **LL accuracy**, therefore to the **odd amplitude**, Regge cuts start contributing at the **NLL order**, to the **even amplitude**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- Write the amplitude as the sum of **odd** and **even component**,

$$\mathcal{M}(s, t) = \mathcal{M}^{(-)}(s, t) + \mathcal{M}^{(+)}(s, t),$$

- with expansion in the strong coupling constant

$$\mathcal{M}^{(\pm)}(s, t) = 4\pi\alpha_s \sum_{l,m} \left(\frac{\alpha_s}{\pi}\right)^l L^m \mathcal{M}^{(\pm,l,m)}.$$

- The (odd) LL contribution to the amplitude is expected to receive **corrections** starting at **NLL**: these are expected to be of the form

$$\mathcal{M}_{ij \rightarrow ij}^{(-)}|_{\text{NLL}} \sim e^{C_A \alpha_g(t) L} Z_i(t) D_i(t) Z_j(t) D_j(t) 4\pi\alpha_s \mathcal{M}_{ij \rightarrow ij}^{(0)},$$

- At NLL,  $\alpha_g(t)$  contains the **first two terms** of its power expansion;  $Z_{i,j}(t)$   $D_{i,j}(t)$  are **impact factors**, representing corrections to the effective **parton-parton-Reggeon vertex**: their power expansion reads

$$Z_i(t) = \sum_{n=0}^{\infty} \left(\frac{\alpha_s}{\pi}\right)^n Z_i^{(n)}(t), \quad D_i(t) = \sum_{n=0}^{\infty} \left(\frac{\alpha_s}{\pi}\right)^n D_i^{(n)}(t).$$

- The impact factors are written in a **factorised form**, according to the **infrared factorisation theorem**:  $Z_{i,j}(t)$  collects the **infrared divergences** of the impact factors.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- What about the **Regge cut** contribution at **NLL**? It involves the exchange of **two Reggeized gluons**, and the **symmetry properties** of this state dictate that it contributes to the **even amplitude**, i.e. to  $\mathcal{M}^{(+)}$ .
- From the point of view of perturbation theory this contribution arises from diagrams like the **two boxes** in the picture above. These diagrams introduce **new color structures** compared to the tree-level color factor.
- Using color-flow space notation, we write the amplitude as a **vector in color space**:

$$\mathcal{M}(s, t) = \sum_i c^{[i]} \mathcal{M}^{[i]}(s, t).$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- It is convenient to decompose the amplitude in a **color orthonormal basis** in the **t-channel**.
- Consider for instance **gluon-gluon** amplitude:

$$8 \otimes 8 = 1 \oplus 8_s \oplus 8_a \oplus 10 \oplus \overline{10} \oplus 27 \oplus 0 \quad \Rightarrow$$

$$c^{[1]} = \frac{1}{N_c^2 - 1} \delta^{a_4 a_1} \delta^{a_3 a_2},$$

$$c^{[8_s]} = \frac{N_c}{N_c^2 - 4} \frac{1}{\sqrt{N_c^2 - 1}} d^{a_1 a_4 b} d^{a_2 a_3 b},$$

$$c^{[8_a]} = \frac{1}{N_c} \frac{1}{\sqrt{N_c^2 - 1}} f^{a_1 a_4 b} f^{a_2 a_3 b},$$

$$c^{[10+\overline{10}]} = \sqrt{\frac{2}{(N_c^2 - 4)(N_c^2 - 1)}} \left[ \frac{1}{2} (\delta^{a_1 a_2} \delta^{a_3 a_4} - \delta^{a_3 a_1} \delta^{a_4 a_2}) - \frac{1}{N_c} f^{a_1 a_4 b} f^{a_2 a_3 b} \right],$$

...

- In this basis the symmetry of the **color structure mirrors** the signature of the corresponding amplitude coefficients, which can thus be separated into **signature odd and even**:

$$\text{odd: } \mathcal{M}^{[8_a]}, \mathcal{M}^{[10+\overline{10}]}, \quad \text{even: } \mathcal{M}^{[1]}, \mathcal{M}^{[8_s]}, \mathcal{M}^{[27]}, \mathcal{M}^{[0]} \quad (gg \text{ scattering}).$$

- The exchange of **one Reggeized gluon** contributes only to the antisymmetric octet, so that at LL only this structure is nonzero:

$$\mathcal{M}_{gg \rightarrow gg}(s, t)|_{LL} = c_{[8_a]} \mathcal{M}^{[8_a]}(s, t)|_{LL}.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- In order to display the **Regge-cut** contributions in the most transparent way, it proves useful to define a “**reduced**” amplitude by removing from it the **Reggeized gluon and collinear divergences** as follows:

$$\hat{\mathcal{M}}_{ij \rightarrow ij} \equiv (Z_i Z_j)^{-1} e^{-\mathbf{T}_t^2 \alpha_g(t) L} \mathcal{M}_{ij \rightarrow ij},$$

- where  $\mathbf{T}_t^2$  represents the colour charge of a Reggeized gluon exchanged in the **t-channel** and  $Z_{i,j}$  stand for collinear divergences. The color operator  $\mathbf{T}_t^2$ , together with other two useful operators  $\mathbf{T}_s^2, \mathbf{T}_u^2$  are defined as

$$\mathbf{T}_s = \mathbf{T}_1 + \mathbf{T}_2 = -\mathbf{T}_3 - \mathbf{T}_4,$$

$$\mathbf{T}_u = \mathbf{T}_1 + \mathbf{T}_3 = -\mathbf{T}_2 - \mathbf{T}_4,$$

$$\mathbf{T}_t = \mathbf{T}_1 + \mathbf{T}_4 = -\mathbf{T}_2 - \mathbf{T}_3.$$

- These operators are subject to color conservation constraints:

$$(\mathbf{T}_1 + \mathbf{T}_2 + \mathbf{T}_3 + \mathbf{T}_4) \mathcal{M} = 0, \quad \mathbf{T}_s^2 + \mathbf{T}_u^2 + \mathbf{T}_t^2 = \sum_{i=1}^4 C_i \equiv C_{\text{tot}}.$$

- In terms of the reduced amplitude, the **NLL** odd contribution reads

$$\hat{\mathcal{M}}_{ij \rightarrow ij}^{(-)} = \left[ 1 + \frac{\alpha_s}{\pi} \left( D_i^{(1)}(t) + D_j^{(1)}(t) \right) \right] 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)}.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- The two-Reggeon cut contribution at NLL reads Caron-Huot, 2013

$$\hat{\mathcal{M}}_{ij \rightarrow ij}^{(+)}|_{\text{NLL}} = i\pi \sum_{\ell=1}^{\infty} \frac{1}{\ell!} \left(\frac{\alpha_s}{\pi}\right)^\ell L^{\ell-1} \times d_\ell \times 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

- where the coefficients  $d_\ell$ s follows from BFKL evolution equation (more later), and have been calculated up to 4 loops:

$$\begin{aligned} d_1 &= \mathfrak{d}_1 \mathbf{T}_{s-u}^2, & \mathfrak{d}_1 &= r_\Gamma \frac{1}{2\epsilon}, \\ d_2 &= \mathfrak{d}_2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2], & \mathfrak{d}_2 &= (r_\Gamma)^2 \left( -\frac{1}{4\epsilon^2} - \frac{9}{2}\epsilon\zeta_3 - \frac{27}{4}\epsilon^2\zeta_4 + \mathcal{O}(\epsilon^3) \right), \\ d_3 &= \mathfrak{d}_3 [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]], & \mathfrak{d}_3 &= (r_\Gamma)^3 \left( \frac{1}{8\epsilon^3} - \frac{11}{4}\zeta_3 - \frac{33}{8}\epsilon\zeta_4 - \frac{357}{4}\epsilon^2\zeta_5 + \mathcal{O}(\epsilon^3) \right), \\ d_4 &= \mathfrak{d}_{4a} [\mathbf{T}_t^2, [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]]] & \mathfrak{d}_{4a} &= (r_\Gamma)^4 \left( -\frac{1}{16\epsilon^4} - \frac{175}{2}\epsilon\zeta_5 + \mathcal{O}(\epsilon^2) \right), \\ &+ \mathfrak{d}_{4b} C_A [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]], & \mathfrak{d}_{4b} &= (r_\Gamma)^4 \left( -\frac{1}{8\epsilon}\zeta_3 - \frac{3}{16}\zeta_4 - \frac{167}{8}\epsilon\zeta_5 + \mathcal{O}(\epsilon^2) \right). \end{aligned}$$

- The color operator  $\mathbf{T}_{s-u}^2 = 1/2(\mathbf{T}_s^2 - \mathbf{T}_u^2)$  is odd under  $s \leftrightarrow u$  crossing.
- At NNLL, the even amplitude is expected to receive corrections, similarly to what happens to the odd amplitude, when going from LL to NLL.  $\rightarrow$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: PERTURBATION THEORY

- **More interesting** are the corrections concerning the **odd amplitude** at **NNLL** accuracy.
- In this case one has to take into account for the first time the exchange of **three Reggeized gluons**. This implies that, starting at **NNLL**, one has **mixing** between **one-** and **three-Reggeons exchange**:

Del Duca, Glover, 2001;  
Del Duca, Falcioni,  
Magnea, LV, 2013

- The mixing between one- and three-Reggeons exchange has significant consequences:
  - It is at the origin of the **breaking** of the **simple power law** one has up to **NLL** accuracy. Such breaking appears for the first time at **two loops**.
  - It implies that, starting at **three loops**, there will be a **single-logarithmic contribution** originating from the **three-Reggeon exchange**, and from the **interference** of the **one- and three-Reggeon exchange**: the interpretation of the **Regge trajectory** at three loops **needs to be clarified**.
- Schematically, the whole amplitude at **NNLL** is composed of

$$\hat{\mathcal{M}}_{ij \rightarrow ij}|_{\text{NNLL}} = \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-)}|_{1\text{-Reggeon} + 3\text{-Reggeon}} + \hat{\mathcal{M}}_{ij \rightarrow ij}^{(+)}|_{2\text{-Reggeon}}.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL THEORY ABRIDGED

- The high-energy limit correspond to a configuration of **forward scattering**:

$$t = (p_1 - p_4)^2 = (p_2 - p_3)^2 = -\frac{s}{2}(1 - \cos \theta),$$

$$u = (p_1 - p_3)^2 = (p_2 - p_4)^2 = -\frac{s}{2}(1 + \cos \theta),$$

$$s \gg -t \quad \Rightarrow \quad \theta \rightarrow 0.$$

- The high-energy logarithm correspond to the **rapidity difference** between the **target** and the **projectile**:

$$\eta = L \equiv \log \left| \frac{s}{t} \right| - i \frac{\pi}{2}.$$

- Such kinematical configuration is described conveniently in terms of **Wilson lines** stretching from  $-\infty$  to  $+\infty$ . The Wilson lines **follow the paths of color charges inside the projectile**, and are thus null and labelled by transverse coordinates  **$\mathbf{z}$** : **Korchenskaya, Korchemsky, 1994, 1996**

$$U(\mathbf{z}_\perp) = \mathcal{P} \exp \left[ ig_s \int_{-\infty}^{+\infty} A_+^a(x^+, x^-=0, \mathbf{z}_\perp) dx^+ T^a \right].$$

- The idea is to approximate, to leading power, the fast projectile and target by Wilson lines and then compute the **scattering amplitude between Wilson lines**. **Babansky, Balitsky, 2002**
- The **full transverse structure** needs to be retained. As a consequence, due to quantum fluctuations, a projectile necessarily contains **multiple color charges at different transverse positions**: the **number** of Wilson lines **cannot be held fixed**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL THEORY ABRIDGED

- However, in perturbation theory, the unitary matrices  $U(z)$  will be **close to identity** and so can be usefully parametrised by a field  $W$ :

$$U(z) = e^{ig_s T^a W^a(z)} .$$

- The color-adjoint field  $W$  sources a **BFKL Reggeised gluon**. A generic projectile, created with four-momentum  $p_1$  and absorbed with  $p_4$ , can thus be expanded at weak coupling as

$$\begin{aligned} |\psi_i\rangle &\equiv \frac{Z_i^{-1}}{2p_1^+} a_i(p_4) a_i^\dagger(p_1) |0\rangle \sim g_s D_{i,1}(t) |W\rangle + g_s^2 D_{i,2}(t) |WW\rangle + g_s^3 D_{i,3}(t) |WWW\rangle + \dots \\ &\equiv |\psi_{i,1}\rangle + |\psi_{i,2}\rangle + |\psi_{i,3}\rangle + \dots \end{aligned}$$

- The factors  $D_{i,j}$  depend on the **transverse coordinates** of the  $W$  fields, but not on the **center of mass energy**. They correspond to the **impact factors** for the exchange of **one-, two- and three-Reggeons**.
- The energy dependence enters from the fact that the Wilson lines have **rapidity divergences** which must be regulated, which leads to a **rapidity evolution equation (Balitsky-JIMWLK)**:

$$-\frac{d}{d\eta} |\psi_i\rangle = H |\psi_i\rangle .$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL THEORY ABRIDGED

- A key feature of the **Balitsky-JIMWLK** equation is that the Hamiltonian is **diagonal** in the **leading approximation**: **Caron-Huot, 2013**

$$H \begin{pmatrix} W \\ WW \\ WWW \\ \dots \end{pmatrix} \equiv \begin{pmatrix} H_{1 \rightarrow 1} & 0 & H_{3 \rightarrow 1} & \dots \\ 0 & H_{2 \rightarrow 2} & 0 & \dots \\ H_{1 \rightarrow 3} & 0 & H_{3 \rightarrow 3} & \dots \\ \dots & \dots & \dots & \dots \end{pmatrix} \begin{pmatrix} W \\ WW \\ WWW \\ \dots \end{pmatrix} \sim \begin{pmatrix} g_s^2 & 0 & g_s^4 & \dots \\ 0 & g_s^2 & 0 & \dots \\ g_s^4 & 0 & g_s^2 & \dots \\ \dots & \dots & \dots & \dots \end{pmatrix} \begin{pmatrix} W \\ WW \\ WWW \\ \dots \end{pmatrix}$$

- After using the rapidity evolution equation to resum all logarithms of the energy, the amplitude is obtained from the **scattering amplitude** between **equal-rapidity Wilson lines**, which depends only on the **transverse scale  $\mathbf{t}$** :

$$\frac{i(Z_i Z_j)^{-1}}{2s} \mathcal{M}_{ij \rightarrow ij} = \langle \psi_j | e^{-HL} | \psi_i \rangle,$$

- Or, in terms of the **reduced amplitude**,

$$\frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij} = \langle \psi_j | e^{-\hat{H}L} | \psi_i \rangle, \quad \hat{H} \equiv H + \mathbf{T}_t^2 \alpha_g(t).$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL THEORY ABRIDGED

- The **inner product** is by definition the scattering amplitude of **Wilson lines** renormalized to **equal rapidity**.
- For our purposes, it suffices to know that it is **Gaussian to leading-order**:

$$G_{11'} \equiv \langle W_1 | W_{1'} \rangle = i \frac{\delta^{a_1 a_1'}}{p_1^2} \delta^{(2-2\epsilon)}(p_1 - p_1') + \mathcal{O}(g_s^2).$$

- **Multi-Reggeon** correlators are obtained by **Wick contractions**:

$$\begin{aligned} \langle W_1 W_2 | W_{1'} W_{2'} \rangle &= G_{11'} G_{22'} + G_{12'} G_{21'} + \mathcal{O}(g_s^2), & \text{Caron-Huot, 2013} \\ \langle W_1 W_2 W_3 | W_{1'} W_{2'} W_{3'} \rangle &= G_{11'} G_{22'} G_{33'} + (5 \text{ permutations}) + \mathcal{O}(g_s^2), \\ &\dots \end{aligned}$$

- There are also off-diagonal elements, which can be **defined** to have **zero overlap** (at equal rapidity):

$$\langle W_1 W_2 W_3 | W_4 \rangle = \langle W_4 | W_1 W_2 W_3 \rangle = 0.$$

- Starting from a scheme in which the inner products is  $\neq 0$ , it is always possible to perform a **scheme transformations** (e.g.  $WWW \rightarrow WWW - g_s^2 G W$ ) such as to reduce to the condition above.
- Choosing the **1-W** and **3-W** states to be orthogonal, combined with symmetry of the Hamiltonian, (**boost invariance**):

$$\frac{d}{d\eta} \langle \mathcal{O}_1 | \mathcal{O}_2 \rangle = 0 \quad \Leftrightarrow \quad \langle H \mathcal{O}_1 | \mathcal{O}_2 \rangle = \langle \mathcal{O}_1 | H \mathcal{O}_2 \rangle \equiv \langle \mathcal{O}_1 | H | \mathcal{O}_2 \rangle,$$

- implies that in this scheme  $H_{k \rightarrow k+2} = H_{k+2 \rightarrow k}$ . This relation is known as **projectile-target duality**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL THEORY ABRIDGED

- We can now list the **ingredients** which build up the amplitude **up to three loops**. Since the odd and even sectors are **orthogonal** and **closed** under the action of  $\hat{H}$  (**signature symmetry**), we have

$$\frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij} \xrightarrow{\text{Regge}} \frac{i}{2s} \left( \hat{\mathcal{M}}_{ij \rightarrow ij}^{(+)} + \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-)} \right) \equiv \langle \psi_j^{(+)} | e^{-\hat{H}L} | \psi_i^{(+)} \rangle + \langle \psi_j^{(-)} | e^{-\hat{H}L} | \psi_i^{(-)} \rangle.$$

- Using that **multi-Reggeon** impact factors are **coupling-suppressed**,  $|\psi_{ik}\rangle \sim g_s^k$ , and using the suppression by powers of  $\alpha_s$  of off-diagonal elements in  $H$ , the signature odd amplitude becomes to three loops:

$$\frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-) \text{ tree}} = \langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{LO})},$$

$$\frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-) \text{ 1-loop}} = -L \langle \psi_{j,1} | \hat{H}_{1 \rightarrow 1} | \psi_{i,1} \rangle^{(\text{LO})} + \langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{NLO})},$$

$$\begin{aligned} \frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-) \text{ 2-loops}} &= +\frac{1}{2} L^2 \langle \psi_{j,1} | (\hat{H}_{1 \rightarrow 1})^2 | \psi_{i,1} \rangle^{(\text{LO})} - L \langle \psi_{j,1} | \hat{H}_{1 \rightarrow 1} | \psi_{i,1} \rangle^{(\text{NLO})} \\ &+ \langle \psi_{j,3} | \psi_{i,3} \rangle^{(\text{LO})} + \langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{NNLO})}, \end{aligned}$$

$$\begin{aligned} \frac{i}{2s} \hat{\mathcal{M}}_{ij \rightarrow ij}^{(-) \text{ 3-loops}} &= -\frac{1}{6} L^3 \langle \psi_{j,1} | (\hat{H}_{1 \rightarrow 1})^3 | \psi_{i,1} \rangle^{(\text{LO})} + \frac{1}{2} L^2 \langle \psi_{j,1} | (\hat{H}_{1 \rightarrow 1})^2 | \psi_{i,1} \rangle^{(\text{NLO})} \\ &- L \left\{ \langle \psi_{j,1} | \hat{H}_{1 \rightarrow 1} | \psi_{i,1} \rangle^{(\text{NNLO})} + \left[ \langle \psi_{j,3} | \hat{H}_{3 \rightarrow 3} | \psi_{i,3} \rangle + \langle \psi_{j,3} | \hat{H}_{1 \rightarrow 3} | \psi_{i,1} \rangle \right. \right. \\ &\quad \left. \left. + \langle \psi_{j,1} | \hat{H}_{3 \rightarrow 1} | \psi_{i,3} \rangle \right]^{(\text{LO})} \right\} + \langle \psi_{j,3} | \psi_{i,3} \rangle^{(\text{NLO})} + \langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{N}^3\text{LO})}. \end{aligned}$$

- Recall that we are considering the **reduced amplitude**: Given that the  $1 \rightarrow 1$  Hamiltonian is equal minus the Regge trajectory, the  $1 \rightarrow 1$  reduced Hamiltonian is actually **zero**, and many terms **vanish**:

$$H_{1 \rightarrow 1} = -C_A \alpha_g(t) \quad \Rightarrow \quad \hat{H}_{1 \rightarrow 1} = 0, \quad \langle \psi_{j,1} | (\hat{H}_{1 \rightarrow 1})^n | \psi_{i,1} \rangle^{(\dots)} = 0.$$

# THE BALITSKY-JIMWLK EQUATION AND THE THREE LOOP AMPLITUDE

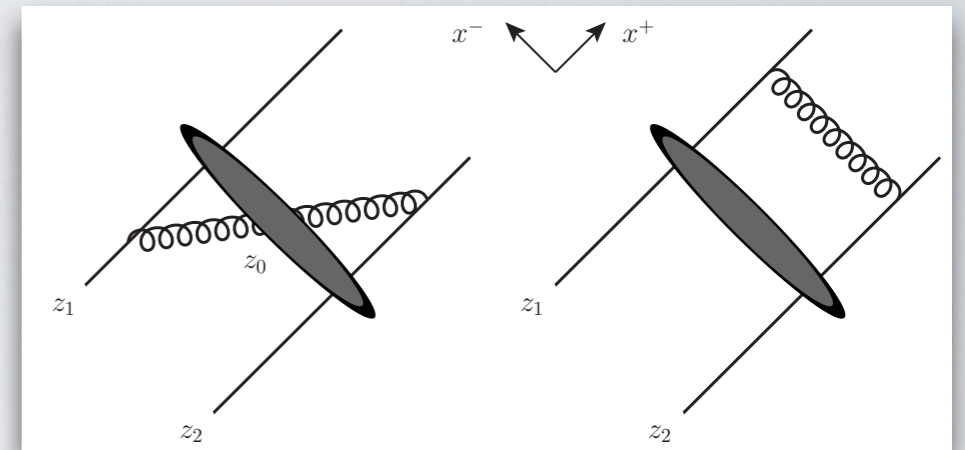

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- The **Balitsky-JIMWLK** equation for an arbitrary number of Wilson lines  $U(z_i)$  can be written in the form

$$-\frac{d}{d\eta} \left[ U(z_1) \dots U(z_n) \right] = \sum_{i,j=1}^n H_{ij} \cdot \left[ U(z_1) \dots U(z_n) \right],$$

- with

**Caron-Huot, 2013**

$$H_{ij} = \frac{\alpha_s}{2\pi^2} \int [dz_i][dz_j][dz_0] K_{ij;0} \left[ T_{i,L}^a T_{j,L}^a + T_{i,R}^a T_{j,R}^a - U_{\text{ad}}^{ab}(z_0) (T_{i,L}^a T_{j,R}^b + T_{j,L}^b T_{i,R}^a) \right] + \mathcal{O}(\alpha_s^2).$$

- We work now in dimensional regularisation with  $2-2\epsilon$  dimensions, and  $dz = d^{2-2\epsilon}z$ , and  $T_{L/R}$ 's are generators for left and right color rotations:

$$T_{i,L}^a = [T^a U(z_i)] \frac{\delta}{\delta U(z_i)}, \quad T_{i,R}^a(z) = [U(z_i) T^a] \frac{\delta}{\delta U(z_i)}.$$

**Balitsky Chirilli, 2013;**  
**Kovner, Lublinsky, Mulian,**  
**2013, 2014, 2016**

- In our analysis we need only the **leading-order** conformal invariant kernel  $K_{ij}$ , which has a very simple dimension-independent expression in momentum space:

$$K_{ij;0} \equiv S_\epsilon(\mu^2) \int [d\vec{q}][d\vec{p}] e^{iq \cdot (z_i - z_0)} e^{ip \cdot (z_j - z_0)} (-2\pi^2) \frac{(q+p)^2}{q^2 p^2} = S_\epsilon(\mu^2) \frac{\Gamma(1-\epsilon)^2}{\pi^{-2\epsilon}} \frac{z_{0i} \cdot z_{0j}}{(z_{0i}^2 z_{0j}^2)^{1-\epsilon}},$$

- The corrections to the **Balitsky-JIMWLK** Hamiltonian are suppressed by  $\alpha_s$  in a power-counting where the Wilson lines are **generic**,  $U \sim 1$ . This is more general than the perturbative counting where  $1 - U \sim g_s W \sim g_s$ , implying that the equation **resums infinite towers of Reggeon iterations**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- To see this, expand  $U$  in powers of  $W$ :

$$U = e^{ig_s W^a T^a} = 1 + ig_s W^a T^a - \frac{g_s^2}{2} W^a W^b T^a T^b - i \frac{g_s^3}{6} W^a W^b W^c T^a T^b T^c + \frac{g_s^4}{24} W^a W^b W^c W^d T^a T^b T^c T^d + \mathcal{O}(g_s^5 W^5).$$

- The expansion of the color generators follows by using the **Backer-Campbell-Hausdorff** formula. Then, it is possible to expand the leading Hamiltonian  $H_{ij}$  in powers of  $g_s$ :

$$H = H_{k \rightarrow k} + H_{k \rightarrow k+2} + \dots$$

- We get

$$H_{k \rightarrow k} = \frac{\alpha_s C_A}{2\pi^2} \int [dz_i][dz_0] K_{ii;0} (W_i - W_0)^a \frac{\delta}{\delta W_i^a} - \frac{\alpha_s}{2\pi^2} \int [dz_i][dz_j][dz_0] K_{ij;0} (W_i - W_0)^x (W_j - W_0)^y (F^x F^y)^{ab} \frac{\delta^2}{\delta W_i^a \delta W_j^b}.$$

- The first **non-linear correction is new**:

$$H_{k \rightarrow k+2} = \frac{\alpha_s^2}{3\pi} \int [dz_i][dz_0] K_{ii;0} (W_i - W_0)^x W_0^y (W_i - W_0)^z \text{Tr}[F^x F^y F^z F^a] \frac{\delta}{\delta W_i^a} + \frac{\alpha_s^2}{6\pi} \int [dz_i][dz_j][dz_0] K_{ij;0} (F^x F^y F^z F^t)^{ab} \left[ (W_i - W_0)^x W_0^y W_0^z (W_j - W_0)^t - W_i^x (W_i - W_0)^y W_0^z (W_j - W_0)^t - (W_i - W_0)^x W_0^y (W_j - W_0)^z W_j^t \right] \frac{\delta^2}{\delta W_i^a \delta W_j^b}.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- More on the **Balitsky-JIMWLK** power counting ( $U \sim 1$ ) vs the **BFKL** power-counting ( $W \sim 1$ ):
- Inserting the expansion of  $U$  in terms of  $W$  in the leading-order **Balitsky-JIMWLK** equation, one finds that an  $m \rightarrow m+k$  transition is proportional to  $g_s^{2l+k}$ . Thus for  $k \geq 0$ , all **the leading interactions can be extracted from the leading-order equation**.

$$H \begin{pmatrix} W \\ (W)^2 \\ (W)^3 \\ (W)^4 \\ (W)^5 \\ \dots \end{pmatrix} \equiv \begin{pmatrix} g_s^2 & 0 & g_s^4 & 0 & g_s^6 & \dots \\ 0 & g_s^2 & 0 & g_s^4 & 0 & \dots \\ g_s^4 & 0 & g_s^2 & 0 & g_s^4 & \dots \\ 0 & g_s^4 & 0 & g_s^2 & 0 & \dots \\ g_s^6 & 0 & g_s^4 & 0 & g_s^2 & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots \end{pmatrix} \begin{pmatrix} W \\ (W)^2 \\ (W)^3 \\ (W)^4 \\ (W)^5 \\ \dots \end{pmatrix} .$$

- On the other hand, interactions with  $k < 0$  are **suppressed by at least  $g_s^{2l+|k|}$** , which means that they can first appear in the  $(|k|+1)$ -loop **Balitsky-JIMWLK** Hamiltonian.
- Thus to obtain the  $m \rightarrow m-2$  transition by **direct calculation** of the Hamiltonian would require **three-loop non-planar computation**.
- For our purposes this is unnecessary, since the **symmetry of  $H$  predicts the result**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- The actual calculation is easier in momentum space: introduce **Fourier transform** of the Reggeon-fields **W**:

$$W^a(p) = \int [dz] e^{-ipz} W^a(z), \quad W^a(z) = \int [d\vec{p}] e^{ipz} W^a(p).$$

- The  $k \rightarrow k$  transitions then read

$$H_{k \rightarrow k} = - \int [dp] C_A \alpha_g(p) W^a(p) \frac{\delta}{\delta W^a(p)} + \alpha_s \int [d\vec{q}][dp_1][dp_2] H_{22}(q; p_1, p_2) W^x(p_1+q) W^y(p_2-q) (F^x F^y)^{ab} \frac{\delta}{\delta W^a(p_1)} \frac{\delta}{\delta W^b(p_2)},$$

- where

$$\begin{aligned} \alpha_g(p) &= \frac{\alpha_s}{\pi} \alpha_g^{(1)}(p^2) + \mathcal{O}(\alpha_s^2) \\ &= -\alpha_s(\mu) S_\epsilon(\mu^2) \int [d\vec{q}] \frac{p^2}{q^2(p-q)^2} + \mathcal{O}(\alpha_s^2) = \frac{\alpha_s(\mu) r_\Gamma}{2\pi\epsilon} \left( \frac{\mu^2}{p^2} \right)^\epsilon + \mathcal{O}(\alpha_s^2), \end{aligned}$$

- is the **Regge trajectory**, and

$$H_{22}(q; p_1, p_2) = \frac{(p_1 + p_2)^2}{p_1^2 p_2^2} - \frac{(p_1 + q)^2}{p_1^2 q^2} - \frac{(p_2 - q)^2}{q^2 p_2^2}.$$

- represents the **BFKL kernel**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- More interesting is the  $1 \rightarrow 3$  ( $3 \rightarrow 1$ ) transition: one has

$$H_{1 \rightarrow 3} = \alpha_s^2 \int [d\vec{p}_1][d\vec{p}_2][dp] \text{Tr}[F^a F^b F^c F^d] W^b(p_1) W^c(p_2) W^d(p_3) H_{13}(p_1, p_2, p_3) \frac{\delta}{\delta W^a(p)},$$

- and by symmetry the  $3 \rightarrow 1$  transition by **symmetry** reads

$$H_{3 \rightarrow 1} = \alpha_s^2 \int [dp_1][dp_2][dp_3] \text{Tr}[F^a F^b F^c F^d] W^d(p_1+p_2+p_3) \frac{\delta}{\delta W^a(p_1)} \frac{\delta}{\delta W^b(p_2)} \frac{\delta}{\delta W^c(p_3)} \times (-1) \frac{(p_1+p_2+p_3)^2}{p_1^2 p_2^2 p_3^2} H_{13}(p_1, p_2, p_3),$$

- with kernel

$$H_{13}(p_1, p_2, p_3) = \frac{2\pi}{3} S_\epsilon(\mu^2) \int [d\vec{q}] \left[ \frac{(p_1+p_2)^2}{q^2(p_1+p_2-q)^2} + \frac{(p_2+p_3)^2}{q^2(p_2+p_3-q)^2} - \frac{(p_1+p_2+p_3)^2}{q^2(p_1+p_2+p_3-q)^2} - \frac{p_2^2}{q^2(p_2-q)^2} \right] = \frac{r_\Gamma}{3\epsilon} \left[ \left( \frac{\mu^2}{(p_1+p_2+p_3)^2} \right)^\epsilon + \left( \frac{\mu^2}{p_2^2} \right)^\epsilon - \left( \frac{\mu^2}{(p_1+p_2)^2} \right)^\epsilon - \left( \frac{\mu^2}{(p_2+p_3)^2} \right)^\epsilon \right].$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- Given the Hamiltonian, all one needs to compute the amplitude are the **target** and **projectile impact factors**:

$$|\psi_i\rangle^{(\text{LO})} = ig \mathbf{T}_i^a W^a(p) - \frac{g^2}{2} \mathbf{T}_i^a \mathbf{T}_i^b \int [d\vec{q}] W^a(q) W^b(p-q) \\ - \frac{ig^3}{6} \mathbf{T}_i^a \mathbf{T}_i^b \mathbf{T}_i^c \int [d\vec{q}_1][d\vec{q}_2] W^a(q_1) W^b(q_2) W^c(p-q_1-q_2) + \mathcal{O}(\text{N}^3\text{LL}),$$

$$|\psi_i\rangle^{(\text{NLO})} = \frac{\alpha_s}{\pi} \left[ ig \mathbf{T}_i^a W^a(p) D_i^{(1)}(p) - \frac{g^2}{2} \mathbf{T}_i^a \mathbf{T}_i^b \int [d\vec{q}] \psi_i^{(1)}(p, q) W^a(q) W^b(p-q) + \mathcal{O}(\text{N}^3\text{LL}) \right],$$

$$|\psi_i\rangle^{(\text{NNLO})} = \left( \frac{\alpha_s}{\pi} \right)^2 \left[ ig \mathbf{T}_i^a W^a(p) D_i^{(2)}(p) + \mathcal{O}(\text{N}^3\text{LL}) \right].$$

- The Wilson line is in the representation of particle  $i$ , and  $p$  in the transferred momentum,  $p^2 = -t$ .
- At higher orders in the coupling, the color charge of the projectile is **no longer concentrated in a single point**, which leads to a **nontrivial momentum dependence** for **multi-Reggeon impact factors**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: ONE AND TWO LOOPS

- To get the **signature-odd** amplitude to **two loops** we need exchanges of **one-** and **three-Reggeons**, the latter first appearing at two loops.

- Let us consider first the **single Reggeon** exchange: to all orders one has

$$\langle \psi_{j,1} | e^{-\hat{H}_{1 \rightarrow 1} L} | \psi_{i,1} \rangle = D_i(t) D_j(t) \frac{i}{2s} 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

- which up to **NNLL** gives

$$\langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{NLO})} = \frac{\alpha_s}{\pi} \left( D_i^{(1)}(t) + D_j^{(1)}(t) \right) \frac{i}{2s} 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

$$\langle \psi_{j,1} | \psi_{i,1} \rangle^{(\text{NNLO})} = \left( \frac{\alpha_s}{\pi} \right)^2 \left( D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} \right) \frac{i}{2s} 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)}.$$

- the **3 → 3** transition appears first at **two loops**: it can be cast into the form

$$\langle \psi_{j,3} | \psi_{i,3} \rangle^{(\text{LO})} = -i\pi^2 (r_\Gamma)^2 \mathcal{I}[1] \frac{g^2}{t} \left( \frac{\alpha_s}{\pi} \right)^2 C_{33}^{(2)}$$

- where the color structure can be written in terms of color **operators acting on the tree-level color structure**:

$$\begin{aligned} C_{33}^{(2)} &= \frac{1}{36} \sum_{\sigma \in \mathcal{S}_3} \left( \mathbf{T}_i^{\sigma(a)} \mathbf{T}_i^{\sigma(b)} \mathbf{T}_i^{\sigma(c)} \right)_{a_1 a_4} \left( \mathbf{T}_j^a \mathbf{T}_j^b \mathbf{T}_j^c \right)_{a_2 a_3} \\ &= \frac{1}{24} \left[ (\mathbf{T}_{s-u}^2)^2 - \frac{1}{12} (C_A)^2 \right] (T_i^b)_{a_1 a_4} (T_j^b)_{a_2 a_3}. \end{aligned}$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: ONE AND TWO LOOPS

- The momentum structure reads

$$\mathcal{I}[N] \equiv \left( \frac{4\pi S_\epsilon(p^2)}{r_\Gamma} \right)^2 \int [d^2p_1][d^2p_2] \frac{p^2}{p_1^2 p_2^2 (p-p_1-p_2)^2} N$$

- Up to **three loops**, the momentum structure is determined in terms of **simple bubble integrals**:

$$\int \frac{d^{2-2\epsilon}k}{(2\pi)^{2-2\epsilon}} \frac{1}{[k^2]^\alpha [(p-k)^2]^\beta} = \frac{B_{\alpha,\beta}(\epsilon)}{(4\pi)^{1-\epsilon}} (p^2)^{1-\epsilon-\alpha-\beta}$$

with

$$B_{\alpha,\beta}(\epsilon) \equiv \frac{\Gamma(1-\alpha-\epsilon)\Gamma(1-\beta-\epsilon)\Gamma(\alpha+\beta-1+\epsilon)}{\Gamma(\alpha)\Gamma(\beta)\Gamma(2-2\epsilon-\alpha-\beta)}.$$

- The **transition** reads

$$\langle \psi_{j,3} | \psi_{i,3} \rangle^{(\text{LO})} = -\frac{\pi^2}{24} \left( \frac{\alpha_s}{\pi} \right)^2 (r_\Gamma)^2 \mathcal{I}[1] \left[ (\mathbf{T}_{s-u}^2)^2 - \frac{1}{12} (C_A)^2 \right] \frac{i}{2s} 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)}.$$

- Up to two loops the amplitude then reads

$$\hat{\mathcal{M}}_{ij \rightarrow ij}^{(-,1)} = \left( D_i^{(1)} + D_j^{(1)} \right) \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

$$\hat{\mathcal{M}}_{ij \rightarrow ij}^{(-,2)} = \left[ D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} \left( + \pi^2 R^{(2)} \left( (\mathbf{T}_{s-u}^2)^2 - \frac{1}{12} (C_A)^2 \right) \right) \right] \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

Three-Reggeon cut

- with

$$R^{(2)} \equiv -\frac{1}{24} (r_\Gamma)^2 \mathcal{I}[1] = -\frac{(r_\Gamma)^2}{6\epsilon^2} \frac{B_{1,1+\epsilon}(\epsilon)}{B_{1,1}(\epsilon)} = (r_\Gamma)^2 \left( -\frac{1}{8\epsilon^2} + \frac{3}{4}\epsilon\zeta_3 + \frac{9}{8}\epsilon^2\zeta_4 + \dots \right),$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THREE LOOPS

- At **three loops** we need to take into account for the first time the  $H_{3 \rightarrow 3}$ ,  $H_{1 \rightarrow 3}$  and  $H_{3 \rightarrow 1}$  evolutions. The action of  $H_{3 \rightarrow 3}$  gives

$$\begin{aligned} & \hat{H}_{3 \rightarrow 3} W^a(p_1) W^b(p_2) W^c(p_3) \Big|_{S^3} \\ & \simeq \frac{\alpha_s r_\Gamma}{2\pi\epsilon} \left[ \mathbf{T}_t^2 - 3C_A \left( \frac{p^2}{p_1^2} \right)^\epsilon \right] W^a(p_1) W^b(p_2) W^c(p_3) \\ & \quad - \alpha_s (\mathbf{T}_t^2 - 3C_A) S_\epsilon \int [d\vec{q}] H_{22}(q; p_1, p_2) W^a(p_1+q) W^b(p_2-q) W^c(p_3), \end{aligned}$$

- which gives rise to the following transition:

$$\begin{aligned} \langle \psi_{j,3} | \hat{H}_{3 \rightarrow 3} | \psi_{i,3} \rangle &= \frac{\pi^2}{48} \left( \frac{\alpha_s}{\pi} \right)^3 (r_\Gamma)^3 \left[ \mathbf{T}_t^2 (2\mathcal{I}_b - \mathcal{I}_a - \mathcal{I}_c) + 3C_A (\mathcal{I}_c - \mathcal{I}_b) \right] \\ & \quad \cdot \left[ (\mathbf{T}_{s-u}^2)^2 - \frac{1}{12} (C_A)^2 \right] \frac{i}{2S} 4\pi\alpha_s \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)}. \end{aligned}$$

- The transition is completely determined in terms of **bubble integrals**:

$$\mathcal{I}_a \equiv \mathcal{I} \left[ \frac{1}{\epsilon} \right] = \frac{4}{\epsilon^3} \frac{B_{1,1+\epsilon}(\epsilon)}{B_{1,1}(\epsilon)} = \frac{3}{\epsilon^3} - 18\zeta_3 - 27\epsilon\zeta_4 + \dots$$

$$\mathcal{I}_b \equiv \mathcal{I} \left[ \frac{1}{\epsilon} \left( \frac{p^2}{p_1^2} \right)^\epsilon \right] = \frac{4}{\epsilon^3} \frac{B_{1+\epsilon,1+\epsilon}(\epsilon)}{B_{1,1}(\epsilon)} = \frac{2}{\epsilon^3} - 44\zeta_3 - 66\epsilon\zeta_4 + \dots$$

$$\mathcal{I}_c \equiv \mathcal{I} \left[ \frac{1}{\epsilon} \left( \frac{p^2}{(p_1 + p_2)^2} \right)^\epsilon \right] = \frac{4}{\epsilon^3} \frac{B_{1,1+2\epsilon}(\epsilon)}{B_{1,1}(\epsilon)} = \frac{8}{3\epsilon^3} - \frac{128}{3}\zeta_3 - 64\epsilon\zeta_4 + \dots$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: THE BALITSKY-JIMWLK EQUATION

- The  $1 \rightarrow 3, 3 \rightarrow 1$  transitions are determined in terms of the same bubble integrals,

$$\langle \psi_{j,3} | \hat{H}_{1 \rightarrow 3} | \psi_{i,1} \rangle + \langle \psi_{j,1} | \hat{H}_{3 \rightarrow 1} | \psi_{i,3} \rangle = \frac{i}{12} \left( \frac{\alpha_s}{\pi} \right)^3 \pi^2 (r_\Gamma)^3 \left[ 2\mathcal{I}_c - \mathcal{I}_a - \mathcal{I}_b \right] \frac{g^2}{t} C_{13+31}^{(3)}.$$

- and the **color structure** reads

$$\begin{aligned} C_{13+31}^{(3)} &\equiv \frac{1}{6} \sum_{\sigma \in \mathcal{S}^3} \text{Tr} [F^a F^{\sigma(b)} F^{\sigma(c)} F^{\sigma(d)}] \left[ (T_i^a)_{a_1 a_4} (T_j^b T_j^c T_j^d)_{a_2 a_3} + (T_i^b T_i^c T_i^d)_{a_1 a_4} (T_j^a)_{a_2 a_3} \right] \\ &= \frac{1}{4} \left( 2\mathbf{T}_{s-u}^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] - [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_{s-u}^2 - (\mathbf{T}_{s-u}^2)^2 C_A - \frac{1}{12} (C_A)^3 \right) (T_i^b)_{a_1 a_4} (T_j^b)_{a_2 a_3} \end{aligned}$$

- Collecting the results, we obtain the three loop contribution to the **odd amplitude**:

$$\hat{\mathcal{M}}_{ij \rightarrow ij}^{(-,3,1)} = \pi^2 \left( R_A^{(3)} \mathbf{T}_{s-u}^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] + R_B^{(3)} [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_{s-u}^2 + R_C^{(3)} (C_A)^3 \right) \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)},$$

- where the loop functions  $R_{A,B,C}$  are

Caron-Huot, Gardi, LV, 2017

$$R_A^{(3)} = \frac{1}{16} (r_\Gamma)^3 (\mathcal{I}_a - \mathcal{I}_c) = (r_\Gamma)^3 \left( \frac{1}{48\epsilon^3} + \frac{37}{24} \zeta_3 + \dots \right),$$

$$R_B^{(3)} = \frac{1}{16} (r_\Gamma)^3 (\mathcal{I}_c - \mathcal{I}_b) = (r_\Gamma)^3 \left( \frac{1}{24\epsilon^3} + \frac{1}{12} \zeta_3 + \dots \right),$$

$$R_C^{(3)} = \frac{1}{288} (r_\Gamma)^3 (2\mathcal{I}_c - \mathcal{I}_a - \mathcal{I}_b) = (r_\Gamma)^3 \left( \frac{1}{864\epsilon^3} - \frac{35}{432} \zeta_3 + \dots \right).$$

# COMPARISON BETWEEN REGGE AND INFRARED FACTORIZATION

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- The prediction for the reduced amplitude is based **solely** on **evolution equations of the Regge limit**, and has taken **no input** from the theory of **infrared divergences**.
- It is therefore a **highly nontrivial consistency test** that this prediction is **consistent** with the known **exponentiation pattern** and the **anomalous dimensions** governing infrared divergences.
- **Conversely**, the prediction for the reduced amplitude can also be seen as a **constraint** on the **soft anomalous dimension**: the high-energy limit of the latter has a very special structure, which may ultimately help in determining it beyond three loops.
- The infrared divergences of scattering amplitudes are controlled by a **renormalization group equation**, whose integrated version takes the form

**Becher, Neubert, 2009; Gardi, Magnea, 2009**

$$\mathcal{M}_n(\{p_i\}, \mu, \alpha_s(\mu^2)) = \mathbf{Z}_n(\{p_i\}, \mu, \alpha_s(\mu^2)) \mathcal{H}_n(\{p_i\}, \mu, \alpha_s(\mu^2)),$$

- where **Z** is given as a path-ordered exponential of the soft-anomalous dimension:

$$\mathbf{Z}_n(\{p_i\}, \mu, \alpha_s(\mu^2)) = \mathcal{P} \exp \left\{ -\frac{1}{2} \int_0^{\mu^2} \frac{d\lambda^2}{\lambda^2} \mathbf{\Gamma}_n(\{p_i\}, \lambda, \alpha_s(\lambda^2)) \right\},$$

- the dependence on the **scale** is both explicit and via the **4 - 2ε** dimensional coupling. The soft anomalous dimension for scattering of massless partons ( $p_i^2 = 0$ ) is an **operators in color space** given, to three loops, by

$$\mathbf{\Gamma}_n(\{p_i\}, \lambda, \alpha_s(\lambda^2)) = \mathbf{\Gamma}_n^{\text{dip.}}(\{p_i\}, \lambda, \alpha_s(\lambda^2)) + \mathbf{\Delta}_n(\{\rho_{ijkl}\}).$$

**Becher, Neubert, 2009; Dixon, Gardi, Magnea, 2009; Del Duca, Duhr, Gardi, Magnea, White, 2011; Neubert, LV, 2012, ...**

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- $\Gamma_n^{\text{dip}}$  involves only **pairwise interactions** amongst the hard partons, and is therefore referred to as the “**dipole formula**”:

$$\Gamma_n^{\text{dip.}}(\{p_i\}, \lambda, \alpha_s(\lambda^2)) = -\frac{\gamma_K(\alpha_s)}{2} \sum_{i < j} \log\left(\frac{-s_{ij}}{\lambda^2}\right) \mathbf{T}_i \cdot \mathbf{T}_j + \sum_i \gamma_i(\alpha_s).$$

- The term  $\Delta_n(\rho_{ijkl})$  involves interactions of up to four partons, and is called the “**quadrupole correction**”:

$$\Delta_n(\{\rho_{ijkl}\}) = \sum_{i=3}^{\infty} \left(\frac{\alpha_s}{\pi}\right)^i \Delta_n^{(i)}(\{\rho_{ijkl}\}).$$

- The **three loop correction** has been calculated recently, and reads

$$\begin{aligned} \Delta_n^{(3)}(\{\rho_{ijkl}\}) = & \frac{1}{4} f^{abe} f^{cde} \sum_{1 \leq i < j < k < l \leq n} \left[ \mathbf{T}_i^a \mathbf{T}_j^b \mathbf{T}_k^c \mathbf{T}_l^d \mathcal{F}(\rho_{ikjl}, \rho_{iljk}) \right. \\ & + \mathbf{T}_i^a \mathbf{T}_k^b \mathbf{T}_j^c \mathbf{T}_l^d \mathcal{F}(\rho_{ijkl}, \rho_{ilkj}) + \mathbf{T}_i^a \mathbf{T}_l^b \mathbf{T}_j^c \mathbf{T}_k^d \mathcal{F}(\rho_{ijlk}, \rho_{iklj}) \left. \right] \\ & - \frac{C}{4} f^{abe} f^{cde} \sum_{i=1}^n \sum_{\substack{1 \leq j < k \leq n, \\ j, k \neq i}} \{\mathbf{T}_i^a, \mathbf{T}_i^d\} \mathbf{T}_j^b \mathbf{T}_k^c, \end{aligned}$$

Almelid, Duhr, Gardi, 2015,2016

- where  $\mathcal{F}$  is a function of **cross ratios**:  $\rho_{ijkl} = \frac{(-s_{ij})(-s_{kl})}{(-s_{ik})(-s_{jl})}$ . Explicitly, one has

$$\mathcal{F}(\rho_{ikjl}, \rho_{ilkj}) = F(1 - z_{ijkl}) - F(z_{ijkl}), \quad \text{with} \quad F(z) = \mathcal{L}_{10101}(z) + 2\zeta_2 \left( \mathcal{L}_{001}(z) + \mathcal{L}_{100}(z) \right),$$

- where the  $\mathcal{L}$  are Brown’s single-valued harmonic polylogarithms, and the **constant term** reads

$$C = \zeta_5 + 2\zeta_2\zeta_3.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- In the **high-energy limit** the **dipole formula** reduces to

Del Duca,  
Duhr,  
Gardi,  
Magnea,  
White,  
2011

$$\Gamma^{\text{dip.}}(\{p_i\}, \lambda, \alpha_s(\lambda^2)) \xrightarrow{\text{Regge}} \frac{\gamma_K(\alpha_s)}{2} \left[ L \mathbf{T}_t^2 + i\pi \mathbf{T}_{s-u}^2 + \frac{C_{\text{tot}}}{2} \log \frac{-t}{\lambda^2} \right] + \sum_{i=1}^4 \gamma_i(\alpha_s) + \mathcal{O}\left(\frac{t}{s}\right),$$

- and the **quadrupole correction** reads:

$$\begin{aligned} \Delta^{(3)} = & i\pi [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \frac{1}{4} \left[ \zeta_3 L + 11\zeta_4 \right] + \frac{1}{4} [\mathbf{T}_{s-u}^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \left[ \zeta_5 - 4\zeta_2\zeta_3 \right] \\ & - \frac{\zeta_5 + 2\zeta_2\zeta_3}{8} \left\{ f^{abe} f^{cde} \left[ \{\mathbf{T}_t^a, \mathbf{T}_t^d\} \left( \{\mathbf{T}_{s-u}^b, \mathbf{T}_{s-u}^c\} + \{\mathbf{T}_{s+u}^b, \mathbf{T}_{s+u}^c\} \right) \right. \right. \\ & \left. \left. + \{\mathbf{T}_{s-u}^a, \mathbf{T}_{s-u}^d\} \{\mathbf{T}_{s+u}^b, \mathbf{T}_{s+u}^c\} \right] - \frac{5}{8} C_A^2 \mathbf{T}_t^2 \right\}, \end{aligned}$$

Only NNLL term

- where

$$\mathbf{T}_{s-u}^a \equiv \frac{1}{\sqrt{2}} (\mathbf{T}_s^a - \mathbf{T}_u^a), \quad \mathbf{T}_{s+u}^a \equiv \frac{1}{\sqrt{2}} (\mathbf{T}_s^a + \mathbf{T}_u^a).$$

Caron-Huot, Gardi, LV, 2017

- Because of the form of  $\Gamma_n^{\text{dip}}$  and  $\Delta_n(\rho_{ijkl})$  in the High-energy limit, the **Z** factor factorises

$$\mathbf{Z}(\{p_i\}, \mu, \alpha_s(\mu^2)) = \tilde{\mathbf{Z}}\left(\frac{s}{t}, \mu, \alpha_s(\mu^2)\right) Z_i(t, \mu, \alpha_s(\mu^2)) Z_j(t, \mu, \alpha_s(\mu^2)),$$

- where the relevant bit for us is

$$\tilde{\mathbf{Z}}\left(\frac{s}{t}, \mu, \alpha_s(\mu^2)\right) = \exp \left\{ K(\alpha_s(\mu^2)) [L \mathbf{T}_t^2 + i\pi \mathbf{T}_{s-u}^2] + Q_{\Delta}^{(3)} \right\}$$

- The factor **K** involve an integral over the scale:

$$K(\alpha_s(\mu^2)) = -\frac{1}{4} \int_0^{\mu^2} \frac{d\lambda^2}{\lambda^2} \gamma_K(\alpha_s(\lambda^2)) = \frac{1}{2\epsilon} \frac{\alpha_s(\mu^2)}{\pi} + \dots,$$

- and the **quadrupole interaction** is contained in the term  $Q_{\Delta}$ :

$$Q_{\Delta}^{(3)} = -\frac{\Delta^{(3)}}{2} \int_0^{\mu^2} \frac{d\lambda^2}{\lambda^2} \left( \frac{\alpha_s(\lambda^2)}{\pi} \right)^3 = \frac{\Delta^{(3)}}{6\epsilon} \left( \frac{\alpha_s(\mu^2)}{\pi} \right)^3.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- The scalar factors  $Z_{i,j}$  are the same as those we removed from the **reduced amplitude** in the **BFKL** context, and at **LL** accuracy the exponent in  $\tilde{Z}$  is also very similar to the **gluon Regge trajectory** subtracted in the reduced amplitude. This makes the relation between the “**infrared-renormalized**” amplitude (hard function)  $H$  and reduced matrix element particularly simple:

$$\mathcal{H}_{ij \rightarrow ij}(\{p_i\}, \mu, \alpha_s(\mu^2)) = \exp^{-1} \left\{ K(\alpha_s(\mu^2)) [L \mathbf{T}_t^2 + i\pi \mathbf{T}_{s-u}^2] + Q_{\Delta}^{(3)} \right\} \\ \cdot \exp \left\{ \alpha_g(t) L \mathbf{T}_t^2 \right\} \hat{\mathcal{M}}_{ij \rightarrow ij}(\{p_i\}, \mu, \alpha_s(\mu^2)).$$

- This equation allows us to pass directly from the **reduced amplitude** predicted using **BFKL theory**, to the **hard function**.
- In particular, the statement that the left-hand-side  $H$  is **finite**, which is equivalent to the **exponentiation of infrared divergences**, is a highly nontrivial constraint on our result.
- By using Baker-Campbell-Hausdorff formula one gets

$$\mathcal{H}_{ij \rightarrow ij}(\{p_i\}, \mu, \alpha_s(\mu^2)) = \left( 1 + \frac{K^3(\alpha_s)}{3!} \left( 2\pi^2 L [\mathbf{T}_{s-u}^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] - i\pi L^2 [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \right) \right. \\ \left. + i\pi \frac{K^2(\alpha_s)}{2} L [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] - Q_{\Delta}^{(3)} \right) \cdot \exp \left\{ -i\pi K(\alpha_s) \mathbf{T}_{s-u}^2 \right\} \\ \cdot \exp \left\{ \left( \alpha_g(t) - K(\alpha_s) \right) L \mathbf{T}_t^2 \right\} \hat{\mathcal{M}}_{ij \rightarrow ij}(\{p_i\}, \mu, \alpha_s(\mu^2)).$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- In the following we expand in powers of  $\alpha_s$  and  $L$ , according to

$$\mathcal{H}_{ij \rightarrow ij}(\{p_i\}, \mu, \alpha_s(\mu^2)) = 4\pi\alpha_s \sum_{n=0}^{\infty} \sum_{k=0}^n \left(\frac{\alpha_s}{\pi}\right)^n L^k \mathcal{H}^{(n,k)}\left(\frac{-t}{\mu^2}\right).$$

- At LL, it is easy to check that one gets

$$\mathcal{H}_{ij \rightarrow ij}^{(n,n)} = \frac{1}{n!} \left(\hat{\alpha}_g^{(1)}\right)^n (\mathbf{T}_t^2)^n \hat{\mathcal{M}}_{ij \rightarrow ij}^{(0)}.$$

- where we introduced the “finite” Regge trajectory

$$\hat{\alpha}_g(t) = \alpha_g(t) - K(\alpha_s), \quad \hat{\alpha}_g(t) = \hat{\alpha}_g^{(n)} \left(\frac{\alpha_s(-t)}{\pi}\right)^n,$$

- and the first two orders read

$$\hat{\alpha}_g^{(1)} = \frac{1}{2\epsilon} (r_\Gamma - 1) = -\frac{1}{4}\zeta_2 \epsilon - \frac{7}{6}\zeta_3 \epsilon^2 + \mathcal{O}(\epsilon^3),$$

$$\hat{\alpha}_g^{(2)} = C_A \left(\frac{101}{108} - \frac{\zeta_3}{8}\right) - \frac{7n_f}{54} + \mathcal{O}(\epsilon).$$

Korchenskaya,  
Korchemsky,  
1994, 1996

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

The analysis proceed in a straightforward way: order by order in  $\alpha_s$  we insert the result from Regge theory, and check consistency with the infrared factorisation formula.

For instance at one loop we have

$$\begin{aligned}\mathcal{H}^{(1,1)} &= \hat{\alpha}_g^{(1)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(0)}, \\ \mathcal{H}^{(1,0)} &= \hat{\mathcal{M}}^{(1,0)} - i\pi K^{(1)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)}.\end{aligned}$$

Explicitly, the real and imaginary part of the NLL term are given by

$$\begin{aligned}\text{Re}[\mathcal{H}^{(1,0)}] &= \hat{\mathcal{M}}^{(-,1,0)}, \\ i \text{Im}[\mathcal{H}^{(1,0)}] &= \hat{\mathcal{M}}^{(+,1,0)} - i\pi K^{(1)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)}.\end{aligned}$$

i.e., from Regge theory,

$$\begin{aligned}\text{Re}[\mathcal{H}^{(1,0)}] &= \left( D_i^{(1)} + D_j^{(1)} \right) \hat{\mathcal{M}}^{(0)}, \\ i \text{Im}[\mathcal{H}^{(1,0)}] &= i\pi \left( \mathfrak{d}_1 - K^{(1)} \right) \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)} = i\pi \hat{\alpha}_g^{(1)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)},\end{aligned}$$

Some coefficients, like the impact factors, are not predicted explicitly from Regge theory: in that case, we can use these equations in the reverse direction, and get

$$D_i^{(1)} = \frac{1}{2} \frac{\text{Re}[\mathcal{H}_{ii \rightarrow ii}^{(1,0)[8_a]}}{\mathcal{H}_{ii \rightarrow ii}^{(0)[8_a]}}.$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- We get:

$$\begin{aligned}
 D_g^{(1)} &= -N_c \left( \frac{67}{72} - \zeta_2 \right) + \frac{5}{36} n_f + \epsilon \left[ N_c \left( -\frac{101}{54} + \frac{11}{48} \zeta_2 + \frac{17}{12} \zeta_3 \right) + n_f \left( \frac{7}{27} - \frac{\zeta_2}{24} \right) \right] \\
 &\quad + \epsilon^2 \left[ N_c \left( -\frac{607}{162} + \frac{67}{144} \zeta_2 + \frac{77}{72} \zeta_3 + \frac{41}{32} \zeta_4 \right) + n_f \left( \frac{41}{81} - \frac{5}{72} \zeta_2 - \frac{7}{36} \zeta_3 \right) \right] + \mathcal{O}(\epsilon^3), \\
 D_q^{(1)} &= N_c \left( \frac{13}{72} + \frac{7}{8} \zeta_2 \right) + \frac{1}{N_c} \left( 1 - \frac{1}{8} \zeta_2 \right) - \frac{5}{36} n_f + \epsilon \left[ N_c \left( \frac{10}{27} - \frac{\zeta_2}{24} + \frac{5}{6} \zeta_3 \right) \right. \\
 &\quad \left. + \frac{1}{N_c} \left( 2 - \frac{3}{16} \zeta_2 - \frac{7}{12} \zeta_3 \right) + n_f \left( -\frac{7}{27} + \frac{\zeta_2}{24} \right) \right] + \epsilon^2 \left[ N_c \left( \frac{121}{162} - \frac{13}{144} \zeta_2 - \frac{7}{36} \zeta_3 + \frac{35}{64} \zeta_4 \right) \right. \\
 &\quad \left. + \frac{1}{N_c} \left( 4 - \frac{\zeta_2}{2} - \frac{7}{8} \zeta_3 - \frac{47}{64} \zeta_4 \right) + n_f \left( -\frac{41}{81} + \frac{5}{72} \zeta_2 + \frac{7}{36} \zeta_3 \right) \right] + \mathcal{O}(\epsilon^3).
 \end{aligned}$$

- The result for the impact factor must satisfy **a nontrivial constraint**:

- **Quark** and **gluon impact factor** extracted from **quark-quark** and **gluon-gluon** amplitude must give the correct **quark-gluon amplitude**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- Proceeding in a similar way, the infrared factorisation at **two loops** predicts

$$\mathcal{H}^{(2,2)} = \frac{1}{2} (\hat{\alpha}_g^{(1)})^2 (\mathbf{T}_t^2)^2 \hat{\mathcal{M}}^{(0)},$$

$$\begin{aligned} \mathcal{H}^{(2,1)} = & \hat{\mathcal{M}}^{(2,1)} + \hat{\alpha}_g^{(1)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(1,0)} + \hat{\alpha}_g^{(2)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(0)} \\ & + i\pi K^{(1)} \left[ \frac{1}{2} K^{(1)} [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] - \hat{\alpha}_g^{(1)} \mathbf{T}_{s-u}^2 \mathbf{T}_t^2 \right] \hat{\mathcal{M}}^{(0)}, \end{aligned}$$

$$\mathcal{H}^{(2,0)} = \hat{\mathcal{M}}^{(2,0)} - \frac{\pi^2}{2} (K^{(1)})^2 (\mathbf{T}_{s-u}^2)^2 \hat{\mathcal{M}}^{(0)} - i\pi \left[ K^{(2)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)} + K^{(1)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(1,0)} \right].$$

- Inserting results from the **Regge theory** one gets

$$\text{Re}[\mathcal{H}^{(2,1)}] = \left[ \hat{\alpha}_g^{(2)} + \hat{\alpha}_g^{(1)} \left( D_i^{(1)} + D_j^{(1)} \right) \right] \mathbf{T}_t^2 \hat{\mathcal{M}}^{(0)},$$

$$i \text{Im}[\mathcal{H}^{(2,1)}] = i\pi \left[ \left( \frac{1}{2} d_2 + \frac{1}{2} (K^{(1)})^2 + K^{(1)} \hat{\alpha}_g^{(1)} \right) [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] + \left( \hat{\alpha}_g^{(1)} \right)^2 \mathbf{T}_t^2 \mathbf{T}_{s-u}^2 \right] \hat{\mathcal{M}}^{(0)}.$$

- for the **NLL** coefficient, which is consistent with infrared factorisation. At **NNLL** we are able to predict the **real part**:

$$\begin{aligned} \text{Re}[\mathcal{H}^{(2,0)}] = & \left[ D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} - \pi^2 R^{(2)} \frac{1}{12} (C_A)^2 \right. \\ & \left. + \pi^2 \left( R^{(2)} + \frac{1}{2} (K^{(1)})^2 + K^{(1)} \hat{\alpha}_g^{(1)} \right) (\mathbf{T}_{s-u}^2)^2 \right] \hat{\mathcal{M}}^{(0)}. \end{aligned}$$

- Here we see explicitly for the first time the appearance of the contribution from the **three-Reggeon cut**: because of it, **Regge factorisation** (interpreted as **exponentiation of the Regge pole**) is **broken** starting at two loops. **Del Duca, Glover, 2001; Del Duca, Falcioni, Magnea, LV, 2013**

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- Our framework can be used to extract the **impact factors at two loops**: this is given by taking the projection of the amplitude onto the **antisymmetric octet component**:

$$2D_g^{(2)} = \frac{\mathcal{H}_{gg \rightarrow gg}^{(2,0)[8_a]}}{\mathcal{H}_{gg \rightarrow gg}^{(0)[8_a]}} - (D_g^{(1)})^2 + \pi^2 R^{(2)} \frac{N_c^2}{12} \left( -\pi^2 \hat{R}^{(2)} \frac{N_c^2 + 24}{4} \right),$$

$$D_q^{(2)} + D_g^{(2)} = \frac{\mathcal{H}_{qg \rightarrow qg}^{(2,0)[8_a]}}{\mathcal{H}_{qg \rightarrow qg}^{(0)[8_a]}} - D_q^{(1)} D_g^{(1)} + \pi^2 R^{(2)} \frac{N_c^2}{12} \left( -\pi^2 \hat{R}^{(2)} \frac{N_c^2 + 4}{4} \right),$$

$$2D_q^{(2)} = \frac{\text{Re}[\mathcal{H}_{qq \rightarrow qq}^{(2,0)[8_a]}]}{\mathcal{H}_{qq \rightarrow qq}^{(0)[8_a]}} - (D_q^{(1)})^2 + \pi^2 R^{(2)} \frac{N_c^2}{12} \left( -\pi^2 \hat{R}^{(2)} \frac{N_c^4 - 4N_c^2 + 12}{4N_c^2} \right).$$

Caron-Huot, Gardi, LV, 2017

- The effect of the **three-Reggeon cut** is evident from the **color-dependent term** in the equations above. Once again, **consistency requires the three equations above to be satisfied simultaneously**.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- At **three loops**, at **LL** and **NLL**, the **infrared factorisation formula** predicts

$$\mathcal{H}^{(3,3)} = \frac{1}{6} \left( \hat{\alpha}_g^{(1)} \right)^3 (\mathbf{T}_t^2)^3 \hat{\mathcal{M}}^{(0)},$$

$$\mathcal{H}^{(3,2)} = \hat{\mathcal{M}}^{(3,2)} + \hat{\alpha}_g^{(1)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(2,1)} + \frac{1}{2} (\hat{\alpha}_g^{(1)})^2 (\mathbf{T}_t^2)^2 \hat{\mathcal{M}}^{(1,0)} + \hat{\alpha}_g^{(1)} \hat{\alpha}_g^{(2)} (\mathbf{T}_t^2)^2 \hat{\mathcal{M}}^{(0)}$$

$$+ i\pi \left( -\frac{1}{2} (\hat{\alpha}_g^{(1)})^2 K^{(1)} \mathbf{T}_{s-u}^2 (\mathbf{T}_t^2)^2 + \frac{1}{2} \hat{\alpha}_g^{(1)} (K^{(1)})^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_t^2 - \frac{1}{6} (K^{(1)})^3 [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \right) \hat{\mathcal{M}}^{(0)}.$$

- which is consistent with **Regge exponentiation** and (dipole) **infrared factorisation**. More in details,

$$\text{Re}[\mathcal{H}^{(3,2)}] = \hat{\alpha}_g^{(1)} \left[ \hat{\alpha}_g^{(2)} + \frac{1}{2} \hat{\alpha}_g^{(1)} \left( D_i^{(1)} + D_j^{(1)} \right) \right] (\mathbf{T}_t^2)^2 \hat{\mathcal{M}}^{(0)} = \mathcal{O}(\epsilon),$$

$$\begin{aligned} i \text{Im}[\mathcal{H}^{(3,2)}] &= i\pi \left[ \frac{1}{6} \left( \mathfrak{d}_3 - (K^{(1)})^3 - 3K^{(1)} (\hat{\alpha}_g^{(1)})^2 - 3(K^{(1)})^2 \hat{\alpha}_g^{(1)} \right) [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \right. \\ &\quad \left. + \frac{1}{2} \hat{\alpha}_g^{(1)} \left( \mathfrak{d}_2 + (K^{(1)})^2 + 2K^{(1)} \hat{\alpha}_g^{(1)} \right) \mathbf{T}_t^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] + \frac{1}{2} (\hat{\alpha}_g^{(1)})^3 (\mathbf{T}_t^2)^2 \mathbf{T}_{s-u}^2 \right] \hat{\mathcal{M}}^{(0)} \\ &= i\pi \left( -\frac{11}{24} \zeta_3 + \mathcal{O}(\epsilon) \right) [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] + \mathcal{O}(\epsilon). \end{aligned}$$

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- At **NNLL**, we see **for the first time** the effect of the **quadrupole correction**:

$$\begin{aligned}
 \mathcal{H}^{(3,1)} &= \hat{\mathcal{M}}^{(3,1)} + \hat{\alpha}_g^{(1)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(2,0)} + \hat{\alpha}_g^{(2)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(1,0)} + \hat{\alpha}_g^{(3)} \mathbf{T}_t^2 \hat{\mathcal{M}}^{(0)} \\
 &+ \frac{\pi^2}{6} \left[ -3\hat{\alpha}_g^{(1)} (K^{(1)})^2 (\mathbf{T}_{s-u}^2)^2 \mathbf{T}_t^2 + (K^{(1)})^3 \left( 2\mathbf{T}_{s-u}^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] + [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_{s-u}^2 \right) \right] \hat{\mathcal{M}}^{(0)} \\
 &+ i\pi \left[ -K^{(1)} \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(2,1)} + \left( \frac{1}{2} (K^{(1)})^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] - K^{(1)} \hat{\alpha}_g^{(1)} \mathbf{T}_{s-u}^2 \mathbf{T}_t^2 \right) \hat{\mathcal{M}}^{(1,0)} \right. \\
 &\quad \left. + \left( K^{(1)} K^{(2)} [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] - K^{(2)} \hat{\alpha}_g^{(1)} \mathbf{T}_{s-u}^2 \mathbf{T}_t^2 - K^{(1)} \hat{\alpha}_g^{(2)} \mathbf{T}_{s-u}^2 \mathbf{T}_t^2 \left( -\frac{\zeta_3}{24\epsilon} [\mathbf{T}_t^2, [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2]] \right) \right) \hat{\mathcal{M}}^{(0)} \right].
 \end{aligned}$$

- The effect is in the **even sector**, therefore we cannot check it **explicitly** with our computation.

However, the calculation of the **odd sector** within **Regge theory** gives

$$\begin{aligned}
 \text{Re}[\mathcal{H}^{(3,1)}] &= \left[ \hat{\alpha}_g^{(3)} + \hat{\alpha}_g^{(2)} \left( D_i^{(1)} + D_j^{(1)} \right) + \hat{\alpha}_g^{(1)} \left( D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} \right) \right] \mathbf{T}_t^2 \hat{\mathcal{M}}^{(0)} \\
 &+ \pi^2 \left[ R_C^{(3)} - \frac{1}{12} \hat{\alpha}_g^{(1)} R^{(2)} \right] (\mathbf{T}_t^2)^3 \hat{\mathcal{M}}^{(0)} + \pi^2 \hat{\alpha}_g^{(1)} \hat{R}^{(2)} \mathbf{T}_t^2 (\mathbf{T}_{s-u}^2)^2 \hat{\mathcal{M}}^{(0)} \\
 &+ \pi^2 \left[ R_A^{(3)} + \frac{1}{6} K^{(1)} \left( 2(K^{(1)})^2 + 3\hat{\alpha}_g^{(1)} K^{(1)} + 3d_2 \right) \right] \mathbf{T}_{s-u}^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \hat{\mathcal{M}}^{(0)} \\
 &+ \pi^2 \left[ R_B^{(3)} - \frac{1}{3} K^{(1)} \left( (K^{(1)})^2 + 3\hat{\alpha}_g^{(1)} K^{(1)} + 3(\hat{\alpha}_g^{(1)})^2 \right) \right] [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)}.
 \end{aligned}$$

- Which is **consistent** with **infrared factorisation**. This is a rather **non-trivial check**, given that the two calculations are done in two completely different ways.

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- The Regge theory we have developed, however, allows us also to get some parts of the finite amplitude. Let's have a more detailed look at the amplitude: we have

$$\begin{aligned} \text{Re}[\mathcal{H}^{(3,1)}] = & \left[ \hat{\alpha}_g^{(3)} + \hat{\alpha}_g^{(2)} \left( D_i^{(1)} + D_j^{(1)} \right) + \hat{\alpha}_g^{(1)} \left( D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} \right) \right. \\ & \left. + C_A^2 \frac{\pi^2}{864} \left( \frac{1}{\epsilon^3} - \frac{15\zeta_2}{4\epsilon} - \frac{175\zeta_3}{2} \right) \right] C_A \hat{\mathcal{M}}^{(0)} \quad \text{Caron-Huot, Gardi, LV, 2017} \\ & + \pi^2 \frac{5\zeta_3}{12} \mathbf{T}_{s-u}^2 [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \hat{\mathcal{M}}^{(0)} + \pi^2 \frac{\zeta_3}{12} [\mathbf{T}_t^2, \mathbf{T}_{s-u}^2] \mathbf{T}_{s-u}^2 \hat{\mathcal{M}}^{(0)} + \mathcal{O}(\epsilon). \end{aligned}$$

- Going to an orthonormal basis in the t-channel, in components we have:

$$\begin{aligned} \text{Re}[\mathcal{H}^{(3,1),[8_a]}] = & \left\{ C_A \left[ \hat{\alpha}_g^{(3)} + \hat{\alpha}_g^{(2)} \left( D_i^{(1)} + D_j^{(1)} \right) + \hat{\alpha}_g^{(1)} \left( D_i^{(2)} + D_j^{(2)} + D_i^{(1)} D_j^{(1)} \right) \right] \right. \\ & \left. + C_A^3 \frac{\pi^2}{864} \left( \frac{1}{\epsilon^3} - \frac{15\zeta_2}{4\epsilon} - \frac{175\zeta_3}{2} \right) - C_A \pi^2 \frac{2\zeta_3}{3} + \mathcal{O}(\epsilon) \right\} \hat{\mathcal{M}}^{(0),[8_a]}, \\ \text{Re}[\mathcal{H}^{(3,1),[10+\bar{10}]}] = & \sqrt{2} C_A \sqrt{C_A^2 - 4} \left\{ \frac{11\pi^2 \zeta_3}{24} + \mathcal{O}(\epsilon) \right\} \hat{\mathcal{M}}^{(0),[8_a]}. \end{aligned}$$

- The antisymmetric octet amplitude cannot be predicted entirely, given the unknown Regge trajectory at three loops; The  $10 + \bar{10}$  component, however, can be predicted exactly, and it agrees with a recent calculation of the gluon-gluon scattering amplitude at three loops in N=4 SYM.

Henn, Mistlberger, 2016

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

- Last, consider the relation between the **three-loop “gluon Regge trajectory”** and the **logarithmic terms** in the three-loop amplitude.
- Starting from three loops the “gluon Regge trajectory” is **scheme-dependent**. Here we **defined** it to be the  $|\rightarrow|$  matrix element of the Hamiltonian  $\alpha_g(t) = -H_{|\rightarrow|}/C_A$ , in the scheme where states corresponding to a **different number of Reggeon are orthogonal**.
- This can be related to fixed-order amplitudes by taking the **logarithm of the amplitude** projected onto the **signature-odd adjoint channel**:

$$\log \frac{\mathcal{M}_{gg \rightarrow gg}^{[8_a]}}{\mathcal{M}_{gg \rightarrow gg}^{(0)[8_a]}} = L \left\{ -H_{|\rightarrow|}(t) + \left(\frac{\alpha_s}{\pi}\right)^3 \pi^2 \left[ N_c \left( -2R_A^{(3)} + 2R_B^{(3)} \right) + N_c^3 R_C^{(3)} \right] \right\} + \mathcal{O}(L^0, \alpha_s^4),$$

- Thanks to a recent calculation of the gluon-gluon amplitude in N=4 SYM, in this theory one has

$$\log \frac{\mathcal{M}_{gg \rightarrow gg}^{[8_a], \mathcal{N}=4}}{\mathcal{M}_{gg \rightarrow gg}^{(0)[8_a]}} \Big|_L = N_c \left[ \frac{\alpha_s}{\pi} k_1 + \left(\frac{\alpha_s}{\pi}\right)^2 k_2 + \left(\frac{\alpha_s}{\pi}\right)^3 k_3 + \dots \right],$$

- where

$$k_1 = \frac{1}{2\epsilon} - \epsilon \frac{\zeta_2}{4} - \epsilon^2 \frac{7}{6} \zeta_3 - \epsilon^3 \frac{47}{32} \zeta_4 + \epsilon^4 \left( \frac{7}{12} \zeta_2 \zeta_3 - \frac{31}{10} \zeta_5 \right) + \mathcal{O}(\epsilon^5), \quad \text{Henn, Mistlberger, 2016}$$

$$k_2 = N_c \left[ -\frac{\zeta_2}{8} \frac{1}{\epsilon} - \frac{\zeta_3}{8} - \epsilon \frac{3}{16} \zeta_4 + \epsilon^2 \left( \frac{71}{24} \zeta_2 \zeta_3 + \frac{41}{8} \zeta_5 \right) + \mathcal{O}(\epsilon^3) \right],$$

$$k_3 = N_c^2 \left[ \frac{11\zeta_4}{48} \frac{1}{\epsilon} + \frac{5}{24} \zeta_2 \zeta_3 + \frac{1}{4} \zeta_5 + \mathcal{O}(\epsilon) \right] + \left[ \frac{\zeta_2}{4} \frac{1}{\epsilon^3} - \frac{15\zeta_4}{16} \frac{1}{\epsilon} - \frac{77}{4} \zeta_2 \zeta_3 + \mathcal{O}(\epsilon) \right].$$

- **Matching these two results** we get

# AMPLITUDES IN THE HIGH-ENERGY LIMIT: BFKL VS INFRARED FACTORISATION

$$-H_{1 \rightarrow 1}^{\mathcal{N}=4\text{SYM}} = N_c \left[ \frac{\alpha_s}{\pi} \alpha_g^{(1)} |_{\mathcal{N}=4\text{SYM}} + \left( \frac{\alpha_s}{\pi} \right)^2 \alpha_g^{(2)} |_{\mathcal{N}=4\text{SYM}} + \left( \frac{\alpha_s}{\pi} \right)^3 \alpha_g^{(3)} |_{\mathcal{N}=4\text{SYM}} + \dots \right],$$

- With

$$\alpha_g^{(1)} |_{\mathcal{N}=4\text{SYM}} = k_1, \quad \alpha_g^{(2)} |_{\mathcal{N}=4\text{SYM}} = k_2,$$

Caron-Huot, Gardi, LV, 2017

- and

$$\alpha_g^{(3)} |_{\mathcal{N}=4\text{SYM}} = N_c^2 \left[ -\frac{\zeta_2}{144} \frac{1}{\epsilon^3} + \frac{49\zeta_4}{192} \frac{1}{\epsilon} + \frac{107}{144} \zeta_2 \zeta_3 + \frac{\zeta_5}{4} + \mathcal{O}(\epsilon) \right] + N_c^0 \left[ 0 + \mathcal{O}(\epsilon) \right].$$

- Even though to three loop accuracy the adjoint amplitude **may look like a Regge pole**, e.g. a pure power-law, **it is actually not**: starting from two-loops it is really **a sum of multiple powers**.
- Simply exponentiating the logarithm of the full amplitude at three loops would predict a definitely incorrect four-loop amplitude.
- The **correct, predictive**, procedure is to exponentiate the action of the **BFKL Hamiltonian**. With the **“trajectory”** fixed as above, this procedure **does not require any new parameter** for the **odd amplitude at NNLL to all loop orders**.

# CONCLUSION

- We have computed the **Regge-cut contribution** to **three loops** through **NNLL** in the **signature-odd sector**.
- Our formalism is based on using the non-linear **Balitsky-JIMWLK rapidity evolution equation** to derive an **effective Hamiltonian** acting on states with a fixed number of **Reggeized gluons**.
- A new effect occurring first at NNLL is **mixing between states with  $k$  and  $k+2$  Reggeized gluons** due non-diagonal terms in this Hamiltonian.
- Our results are **consistent** with a recent determination of the **infrared structure of scattering amplitudes at three loops**, as well as a computation of  **$2 \rightarrow 2$  gluon scattering** in  **$N = 4$  super Yang-Mills theory**.
- Combining the latter with our Regge-cut calculation we **extract the three-loop Regge trajectory** in this theory.
- Our results open the way to predict **high-energy logarithms** through **NNLL** at **higher-loop orders**.
